Abstract

Background: Posttraumatic stress disorder (PTSD) is a mental disorder after traumatic events and is characterized by repeated experience of a trauma with disturbing recurring reflections, avoidance or numbing of memories of the event and hyper-arousal. Due to the high prevalence it has attracted much attention in the past years. The etiology is unclear and new treatment methods are urgently required. Various recipes of Chinese herbs are successfully used in Asian countries against mental disorders. For example, *Free and Easy Wanderer* (FAEW) has been a complex herbal mixture for treating mental disorders in China for centuries, but its mode of action is still unclear. **Method:** We conducted the following studies to elucidate the mechanisms of FAEW: (1) we have chosen a "reverse pharmacology" approach and initially used clinical data to verify identified potential PTSD mechanisms in subsequent *in vitro* and *in silico* studies. For this purpose, microarray-based transcriptome-wide mRNA expression profiles of PTSD patients were analyzed, the effect of FAEW and the clinically established antidepressant fluoxetine on the transcription factor NF- κ B using reporter cell assays and Western blotting was investigated. (2) We investigated the neuroprotective effect of FAEW under oxidative stress and the underlying mechanism by microarray and Western blot experiments. (3) We identified various potential drugs by molecular docking and literature research based on the phytochemical components of FAEW. **Results:** FAEW showed high anti-inflammatory activity by inhibiting NF- κ B. PTSD-associated oxidative stress was induced by hydrogen peroxide in the experiment. Here it was shown that FAEW counteracts oxidative stress through KEAP1-NRF2/HO-1 pathway. Paeoniflorin, albiflorin, baicalin, isoliquiritin and liquiritin *in silico* bound with high affinity to the proteins I κ K, p65 and KEAP1. **Conclusion:** FAEW has a variety of drugs and is active against inflammation by inhibition of NF- κ B and against oxidative stress by activation of KEAP1-NRF2/HO-1 signaling pathway, which could be relevant mechanisms of *Free and Easy Wanderer* in the treatment of mental disorders.

Key words: *Free and Easy Wanderer*, posttraumatic stress disorder, inflammation, oxidative stress, NF- κ B, KEAP1-NRF2/HO-1

Zusammenfassung

Hintergrund: Die posttraumatische Belastungsstörung (PTSD) ist eine psychische Störung nach traumatischen Ereignissen und ist gekennzeichnet durch wiederholtes Erleben eines Traumas mit störenden wiederkehrenden Rückblenden und Verhinderung oder Betäubung von Erinnerungen an das Ereignis. Aufgrund der hohen Prävalenz hat sie in den vergangenen Jahren viel Aufmerksamkeit erregt. Die Ätiologie ist ungeklärt und neue Behandlungsmethoden sind dringend erforderlich. Verschiedene Rezepturen chinesischer Kräuter werden in asiatischen Ländern mit Erfolg gegen psychische Störungen eingesetzt. Beispielsweise stellt *Free and Easy Wanderer* (FAEW) seit Jahrhunderten in China eine komplexe Kräutermischung zur Behandlung psychischer Störungen dar, deren Wirkungsweise jedoch immer noch unklar ist. **Methode:** Wir haben folgende Untersuchungen durchgeführt, um den Mechanismen von FAEW aufzuklären: (1) Wir haben einen „reverse pharmacology“ Ansatz gewählt und zunächst klinische Daten herangezogen, um identifizierte potenzielle PTSD-Mechanismen in nachfolgenden *in vitro* und *in silico* Untersuchungen zu verifizieren. Dazu wurden Mikroarray-basierte Transkriptom-weite mRNA-Expressions-Profile von PTSD-Patienten analysiert und die Wirkung von FAEW und dem klinisch etablierten Antidepressivum Fluoxetin auf den Transkriptionsfaktor NF- κ B unter Verwendung von Reporterzell-Assays und Western-Blotting untersucht. (2) Wir haben den neuroprotektiven Effekt von FAEW unter oxidativem Stress und den zugrundeliegenden Mechanismus mittels Mikroarray- und Western-Blot Versuchen untersucht. (3) Wir haben die potenziellen Wirkstoffe durch molekulares Docking und Literaturrecherchen auf der Basis der phytochemischen Bestandteile von FAEW identifiziert. **Ergebnisse:** FAEW zeigte eine hohe anti-entzündliche Aktivität durch Hemmung von NF- κ B. PTSD-assoziiierter oxidativer Stress wurde durch Wasserstoffperoxid-Applikation im Experiment simuliert. Hier zeigte sich, dass FAEW oxidativem Stress durch den KEAP1-NRF2 / HO-1-Weg entgegenwirkt. Paeoniflorin, Albiflorin, Baicalin, Isoliquiritin und Liquiritin *in silico* banden mit hoher Affinität an die Proteine I κ B, p65 und KEAP1. **Schlussfolgerung:** FAEW hat eine Vielzahl von Wirkstoffen und besitzt eine hohe anti-entzündliche Aktivität durch Hemmung von NF- κ B und Aktivierung des anti-oxidativen KEAP1-NRF2 / HO-1 Signalweges. Diese könnten relevante Mechanismen bei der Behandlung von psychischen Störungen darstellen.

Stichwörter: *Free and Easy Wanderer*, posttraumatische Belastungsstörung, Entzündung, oxidativer Stress, NF- κ B, KEAP1-NRF2/HO-1

IPT	interpersonal Psychotherapy

Abbreviation	Connotation
IVR	intervening region
I κ B	inhibitor of κ B
I κ K	inhibitor kappa B kinase
KEAP1	Kelch-like ECH-associated protein 1
K-SADS-PL	Kiddie-SADS-Present and Lifetime Version
LPS	Lipopolysaccharide
LZ	leucine zipper
MS	mass spectrometry
NBD	NEMO-binding domain
NEMO	NF- κ B essential modulator
NET	Narrative Exposure Therapy
NFE2L2	nuclear factor erythroid 2-like 2 (alias NRF2)
NF- κ B	nuclear factor ‘kappa light chain enhancer’ of activated B-cells
NMR	nuclear magnetic resonance-mass spectrometry
NRF2	NF-E2 related factor 2 (alias NFE2L2)
NTR	N-terminal region
PBS	phosphate buffered saline
PCL-C	PTSD Checklist-Civilian Version
PDB	protein database
PTSD	posttraumatic stress disorder
PTSD-SS	Post-traumatic Stress Disorder Self-Rating Scale
RCTs	Randomized Controlled Trials
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
SCID-I/P	Structured Clinical Interview for DSM-IV-TR Axis I Disorder-Patient Edition
SNPs	single nucleotide polymorphisms
TBP	TATA-binding protein
TCM	Traditional Chinese Medicine
TFCBT	trauma-focused cognitive behavior therapy
TNF- α	tumor necrosis factor alpha
TSCC-A	Trauma Symptom Checklist for ChildrenAlternate Version
TSR	trauma spectrum response
VMD	Visual Molecular Dynamics
VRET	virtual reality exposure therapy
ZF	zinc finger

1 Introduction

1.1 General information about PTSD

Posttraumatic stress disorder (PTSD) may develop after a person is exposed to a traumatic event, it is characterized by repeatedly experiencing trauma with disturbing recurring flashbacks, avoidance or numbing of memories of the event, and hyper-arousal [1-3]. It was first recognized as a distinct disease among US-American Vietnam veterans and became popular due to high incidence and complex risk factors. The life time prevalence of PTSD in adults is 7.8%, women have a higher risk than men (20.4% vs. 8.2%)[4, 5]. PTSD is widely affected among earthquake survivors and victims who experienced other traumatic events such as sexual abuse in childhood [2], rape [6], accidents, or terroristic acts [1, 7].

PTSD was included into the third edition of the Diagnostic and Statistical Manual of Mental Disorders (DSMIII) by American Psychiatric Association (APA) in 1980 and continued to be listed in the subsequent editions, that is, DSM-III, DSM-III-Revised (DSM-III-R), DSM fourth edition (DSM-IV), and DSM-IV text revision (DSM-IV-TR). The latest edition is DSM fifth edition (DSM-5) published in 2013, superseding the DSM-IV-TR, which was published in 2000. DSM-5 reveals some difference compared to the former versions. PTSD is not enlisted in the chapter “anxiety disorders” but as single chapter entitled “Trauma- and stressor-related diseases together with acute stress disorder and adaptation disorder”. In DSM-5, the diagnosis criteria are further elaborated. For instance, Criterion A (stressor criterion) focuses more on the circumstances, how a person experiences a traumatizing event. In addition to DSM-5 produced, the International Classification of Diseases (ICD-10) produced by the World Health Organization (WHO) was also a widely established system to classify mental disorders. For example, the Chinese Classification of Mental Disorders (CCMD-III) edited by the Chinese Psychiatric Association in 2000 was used for PTSD diagnosis in China.

1.2 Epidemiology of PTSD

Incidence and prevalence were two commonly used words in the epidemiology of diseases, to make it clear: Incidence is “the number of instances of illness commencing or of persons becoming ill” (or dying or being hurt in injuries or whatever) “during a given period in a specified population”[8]. While prevalence gives a figure for a factor at a single point in time and tells us only what is happening at a certain point[9], most of the reports used the term “prevalence”, not “incidence” for several months lasting aftershock period. **Figure 1** shows the prevalence of PTSD among US adult population with 3.5%, which was published in 2005, and the age stage between 45 and 59 took the highest lifetime prevalence rate. **Table 1** gave an overview of the prevalence and risk factors for PTSD among *Wenchuan* earthquake survivors in China. According to the

analysis, **Figure 2** shows the correlation between PTSD prevalence (in percentage) and time after earthquake (in months) in (A) adults and (B) children and adolescents, correlations between PTSD prevalence (in percentage) and distance (in kilometer) from the epicenter of the earthquake in (C) the whole population and (D) children and adults. A variety of factors could increase the risk for PTSD among *Wenchuan* earthquake survivors, such as economic status, physical injury, age and so on.

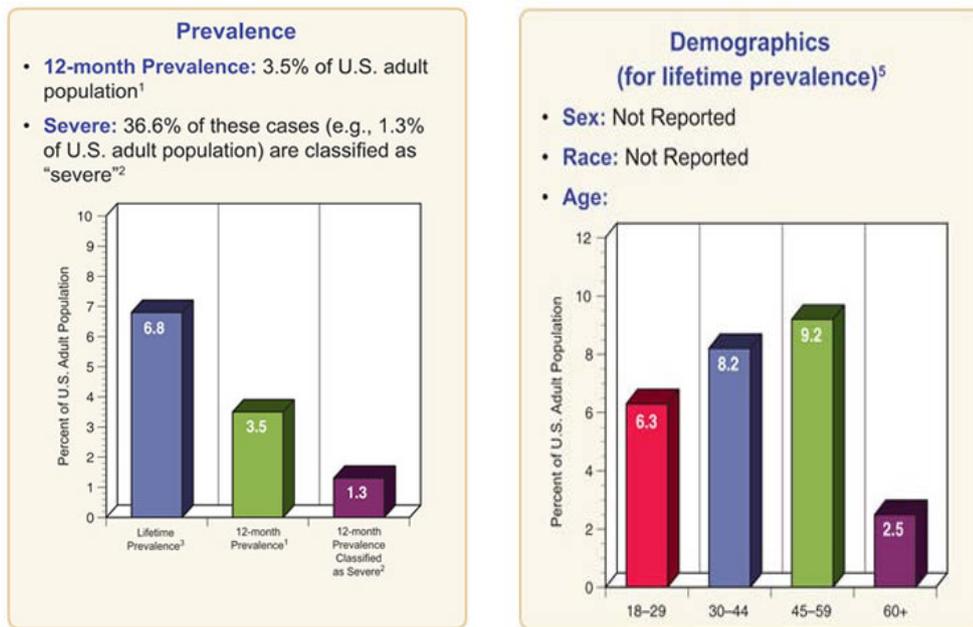

Figure 1. Estimated national PTSD prevalence and demographics for lifetime prevalence in the US in 2012. Image taken from Kessler [10, 11]

Table 1. PTSD Among *Wenchuan* Earthquake Survivors in China.

Time	Place	Sample Size	Population	Estimated PTSD Prevalence	PTSD Diagnostic Tools	Risk factors for PTSD	Associated Disease	Reference
1	Yanjing village of Qingping	1321	Whole	18.7%	IES-R	Low educational level, lacking social support, mudslide exposure, age, living with children under age 6, gender		[12]
1	Qiaozhuang town in Qingchuan county	409	Whole	62.8%	PTSD-SS	Married status, female gender, having deaths or injury of family members, low education level, and losses of possessions		[13]
12	Beichuan County	1195	Whole	26.3%	PCL-C	Bodily injury, loss of livelihood and initial fear	Depression, anxiety	[14]
36	the seriously hard-hit counties; the less-hit counties	2525	Whole	8.8%; 0.5%	PCL-C	Displacement, no regular income, receiving mental health support after the disaster, family members died or missing, injured due to the quake, and person who witnessed someone being killed or injured		[15]
36	Beichuan	287	Whole	22.65%	CAPS	Being female, being widowed, having a low level of education, having low monthly income, suffering bodily injury, being bereaved, and having a low level of social support		[16]
1	Chengdu	324	Secondary students	22.3%	CRIES	Social/emotional support from teachers or peers; exposure to positive news reports, prior experience of severe mental distress and corporal punishment, worry about future aftershocks, absence from school when it was not closed, exposures to scary or sorrowful disaster media coverage, post-disaster visits to affected sites, separation from parents	Depression, suicidal ideation	[17]
1	Chengdu	3323	High school students	22.3%	CRIES	Younger respondents (aged below 15 years)		[18]
6	Dujiangyan	2250	Adolescents	15.8%	PTSD-SS	Female gender, older age, and earthquake disaster exposure	Depression, anxiety	[19]
6	Mianzhu	3208	Adolescents	2.5%	K-SADS-PL, CRIES	Social support, cognitive style, being female, being buried / injured during the earthquake, having parents who were severely injured, having classmate(s) who died, having a house destroyed, and witnessing someone buried / wounded /dying during the earthquake		[20]
10	Ningqiang county	1841	Junior middle school students	28.4%	CRIES	Females and in the severe exposure group, house had been destroyed or severely damaged		[21]

1.3 Mechanisms of PTSD

Dysregulated hypothalamic-pituitary-adrenal (HPA) axis is associated with numerous psychosomatic and psychiatric disorders [42-44]. A wide range of HPA axis changes occurred among PTSD patients, including elevated levels of the corticotrophin-releasing hormone (CRH) / corticotrophin -releasing hormone receptor 1 (CRH type 1 receptor, CRHR1) system [45-47], low cortisol level [48], and increased sensitivity of glucocorticoid [49]. In addition, other biochemical changes were also involved. High catecholamine secretion into urine [50], low serotonin and dopamine levels may also contribute to PTSD [51]. Single nucleotide polymorphisms (SNPs) and epigenetics studies supported their involvement. For instance, DNA methylation in the promoter regions of immune genes, catechol-O-methyl transferase (COMT) and brain-derived neurotrophic factor (BDNF) have been demonstrated to be associated with PTSD [52-54]. In my thesis, I am going to introduce the participation of inflammatory process and oxidative stress, and explore the underlying mechanisms.

1.3.1 Inflammation in PTSD

As a part of the complex biological response of body tissues to harmful stimuli, such as pathogens, damaged cells, or irritants, inflammation is a protective response involving immune cells, blood vessels, and molecular mediators [55]. The function of inflammation is to eliminate the initial

cause of cell injury, clear out necrotic cells and tissues damaged from the original insult, and to initiate tissue repair. Increasing evidence revealed the involvement of immune system in stress-related diseases [56, 57]. Among the diverse diseases, the action mode of inflammation in mental disorders has been demonstrated in previous studies with the participation of C reactive protein or interleukin (IL) [58, 59]. Here in my studies, I am going to focus on nuclear factor of κ B (NF- κ B) pathway and the underlying mechanism in mental disorders.

1.3.1.1 NF- κ B pathway

NF- κ B plays a crucial and evolutionarily conserved role in immunity[60, 61]. Under normal conditions, NF- κ B is inactivated through interaction with inhibitor protein of the I κ B family. Upon activation, NF- κ B is involved in the regulation of genes that impact not only on immune responses but also cell proliferation, survival and differentiation.

The NF- κ B family of transcription factors can be divided into two classes: the NF- κ B proteins (p105/p50 or NFKB1 and p100/p52 or NFKB2) and the Rel proteins (c-Rel, RelB, and RelA/p65)[62]. They are five structurally related protein subunits that share affinity for the κ B DNA sequence motif [60, 63]. Through proteasome-mediated proteolysis, p105 and p100 are processed into the shorter DNA-binding subunits called p50 and p52, respectively [64, 65]. The Rel proteins are distinguished by C-terminal transcriptional activation domains (TAD) [66], while all five NF- κ B/Rel subunits contain the N-terminal Rel homology domain (RHD), essential for DNA binding, dimerization, inhibitor of κ B (I κ B) interaction, and nuclear localization [67-69].

The regulation of NF- κ B includes the canonical and non-canonical pathways (**Figure 3**). The canonical NF- κ B transcription factor, a dimer composed of a p50 and RelA/p65 subunit, will be activated by intracellular or extracellular signals upon the induction of tumor necrosis factor alpha (TNF- α), IL-1, lipopolysaccharide (LPS), viral double-stranded RNA, and ionizing radiation [70, 71], which induced of the I κ B kinase (I κ K) complex. I κ B is phosphorylated at serine 32 and 36 by the I κ K complex, and degraded by proteasome, which consequently frees the canonical NF- κ B dimer to translocate into the nucleus and activate gene transcription. As well as the canonical pathway, upon the induction of TNF receptor family members, NF- κ B-inducing kinase was activated, which promotes an IKK α homodimer, leading to p100 processing into the active p52 subunit. Ultimately, processing of p100 results in the generation of non-canonical transcription factor, a 52-RelB dimer, which is then able to move onto available κ B DNA binding sites and control gene expression of its related genes[72].

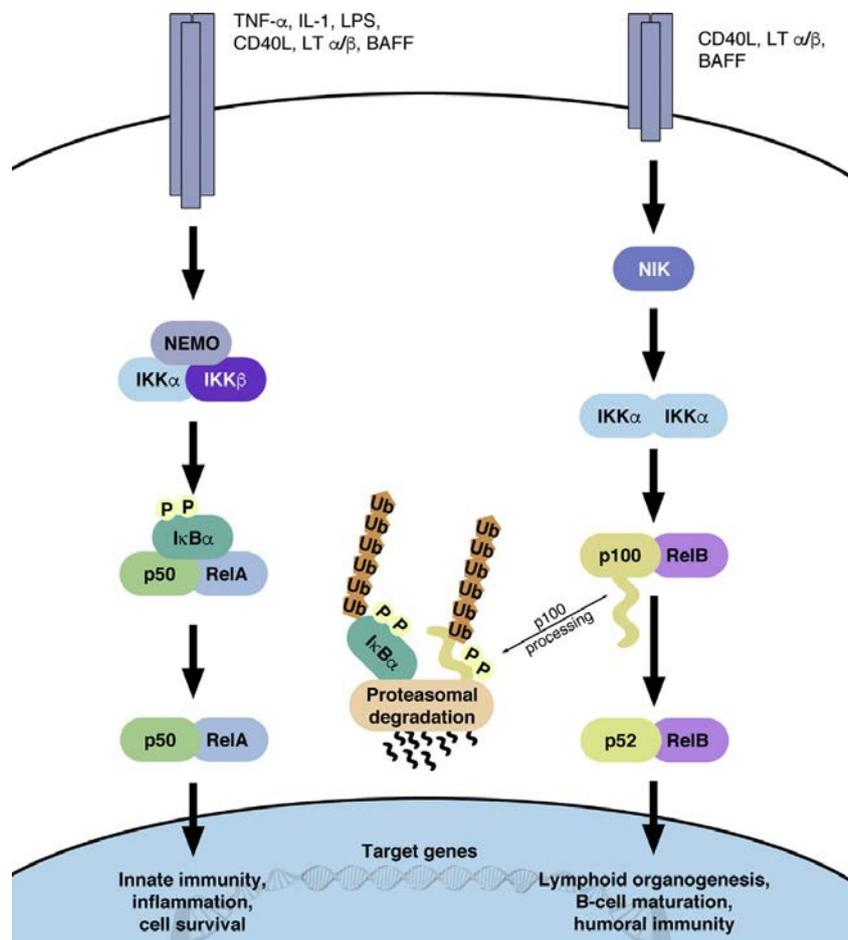

Figure 3. The canonical and non-canonical NF- κ B pathways. Image taken from Durand and Baldwin[73].

1.3.1.2 Drug targets towards NF- κ B pathway

Due to the prominent role of NF- κ B signaling pathway in inflammatory disease and possible links to cancer and autoimmune diseases, drug development to inhibit NF- κ B has been widely performed by industry [74]. To achieve the aim, a variety of strategies can be used to inhibit this pathway, shown in **Figure 4**, they are (i) inhibition of the receptors at the cell surface membrane such as IL-1R and TNFR, (ii) inhibition of I κ K complex, (iii) stabilizing the suppressor protein I κ B[75], (iv) interference with the nuclear transport of NF- κ B, (v) inhibition of DNA binding of NF- κ B proteins. Among the diverse targets, inhibiting I κ K complex and NF- κ B are most common and two specific mechanisms among natural products against inflammation.

I κ K complex is the essential part of NF- κ B translocation, demonstrating the crucial role, which has been an attractive target. I κ K complex is composed of three main components, they are I κ K1 (I κ K α), I κ K2 (I κ K β), and NF- κ B essential modulator (NEMO) (I κ K γ) [76, 77]. The two kinases of the I κ K complex, both I κ K1 and I κ K2 have a kinase domain with two serine residues (S176, S180 for I κ K1 and S177, S181 for I κ K2) that require phosphorylation for the kinase functions, a predicted leucine zipper (LZ) domain and a helix-loop-helix (HLH) domain (29), and a C-terminus NEMO-binding domain (NBD). They share 51% of their sequence identities with highly homologous [78-81]. Many compounds have been screened to select for inhibition of I κ K's kinase

activity. For example, Bay 65-1942 (Compound A) is another highly selective ATP-competitive I κ K β inhibitor that shows broad anti-inflammatory and anticancer activity[82].

Apart from inhibiting the kinase activity of I κ K1 and I κ K2, another approach is to target protein-protein interactions between the I κ K complex members. NEMO is comprised of two coil-coil domains (CC), a LZ, and a zinc finger (ZF) domain. Structural data indicate that dimers of NEMO bind to both I κ K1 and I κ K2 homo- as well as hetero-dimers [83, 84]. The N-terminal portion of NEMO interacts with the NBD of the I κ Ks and such interaction is required for I κ K activation. Phosphorylation of NEMO on S68, which is located in the region that interacts with I κ Ks can down-regulate NF- κ B activation in the presence of stimuli [85, 86], providing the possibility that phosphorylation of NEMO serves as a negative regulatory event. Cell-permeable NEMO-binding domain (NBD) peptide, derived from the NBD of I κ K β , prevents I κ K from binding to NEMO, and inhibits TNF-induced activation of the canonical pathway[87].

In addition, the direct inhibition towards NF- κ B transcription factor is another strategy, which could be achieved through inhibiting the DNA binding sites. Dimethylfumarate (DMF) is an anti-inflammatory drug in clinical use for multiple sclerosis through inhibiting the NF- κ B pathway[88]. DMF blocks NF- κ B activity by covalently modifying RelA/p65 at Cys38, which prevents RelA/p65 nuclear translocation and attenuates its DNA-binding activity [89].

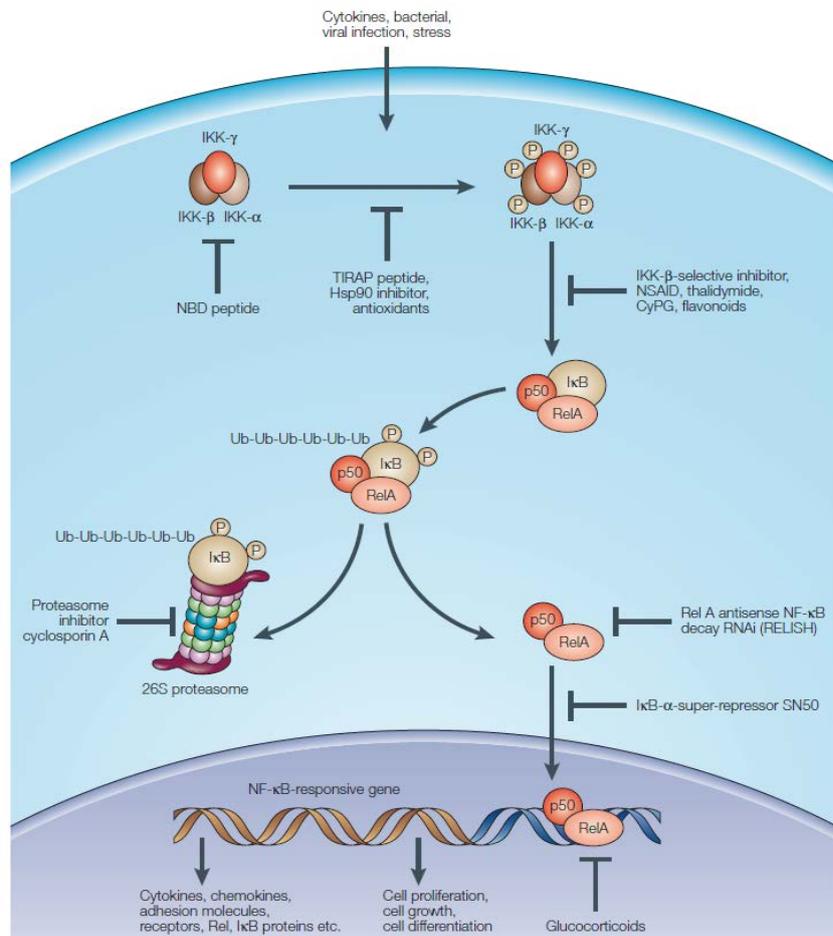

Figure 4. The possible drug targets towards NF- κ B pathways. Image taken from Karin, Yumi Yamamoto and Wang[90].

1.3.2 Oxidative stress

Oxidative stress occurs if molecular defense system fails to counteract oxidation caused by endogenous processes such as the mitochondrial breakdown of glucose for energy supply or by exogenous xenobiotic chemicals, air pollution and diet. It reflects the imbalance of a biological system's ability to detoxify reactive intermediates or repair resulting damage. A growing body of studies demonstrated the involvement of oxidative stress in mental disorders, oxidative damage in the brain of the patients suffering from major mental disorders has been demonstrated be one of the major pathological processes[91]. Elevated lipid peroxidation were shown in the patients of generalized anxiety disorder as well as suppressed antioxidant activity in panic disorder[92]. Rats under stressed conditions exhibited anxiety-like behavior and elevated ROS levels, and *vice versa*, induction of ROS generation resulted in anxiety-like behavior [93]. These observations suggest a causative link between ROS and mental disorders. The link between oxidative stress-related genes and stress-related phenotypes have also been determined by a genome-wide association studies (GWAS) of PTSD[94]. Recently, a novel locus in the oxidative stress-related gene *ALOX12* has been identified [95]. In Addition, nuclear factor erythroid 2-related 2 (NFE2L2 or NRF2) -dependent persistent oxidative stress was demonstrated to cause stress-induced vulnerability to depression in rats[96]. In my thesis, I am going to focus on NRF2 as the underlying mechanism of oxidative stress in mental disorders.

1.3.2.1 NRF2

The multifunctional regulator NRF2 is composed of six functional domains with 605 amino acid known as NRF2-ECH homologies (Neh) and designated as Neh1-6, respectively [97]. Neh1 has a bZip motif responsible for hetero-dimerization with small Maf protein, NRF2-Maf heterodimer then binds to ARE activating gene expression. The Neh2 domain at the N -terminus contains DLG and ETGE motifs that bind to the Kelch-like ECH associated protein 1 (KEAP1) Kelch domain, which negatively regulates the transcriptional activity of NRF2. Domains Neh3 at the C-terminus, Neh4, and Neh5 mediate NRF2 trans-activation by binding to histone acetyltransferases. Neh6 has a function of KEAP1-independent negative regulation of NRF2.

NRF2 is a basic leucine zipper (bZIP) transcription factor that regulates the expression of antioxidant proteins to protect against oxidative damage. NRF2 modulates the expression of well-known antioxidant enzymes, such as heme oxygenase-1 (HO-1) and glutathione S-transferases (GST), but also a large number of genes that seemingly control disparate processes such as immune and inflammatory responses, tissue remodeling and fibrosis, even cognitive dysfunction and addictive behavior [98, 99]. To this end, NRF2 is referred to as a “master regulator” of antioxidant response and is involved in many diseases.

1.3.2.2 KEAP1-NRF2-ARE pathway

NRF2 is differently regulated in various situations according to the conditions (Shown in **Figure 5**). Under normal physiological conditions, NRF2 is sequestered in the cytosol and maintained at a low level through KEAP1-dependent ubiquitination and proteasome degradation. In the presence of oxidative stress, such as ROS or electrophilic chemicals, the cysteine residues of KEAP1 are covalently modified. These chemical modifications result in conformational changes in KEAP1 that relieve NRF2 from KEAP1-directed degradation. NRF2 translocates to the nucleus and activates ARE-dependent gene expression of a series of anti-oxidative and cytoprotective proteins, such as HO-1 [100, 101].

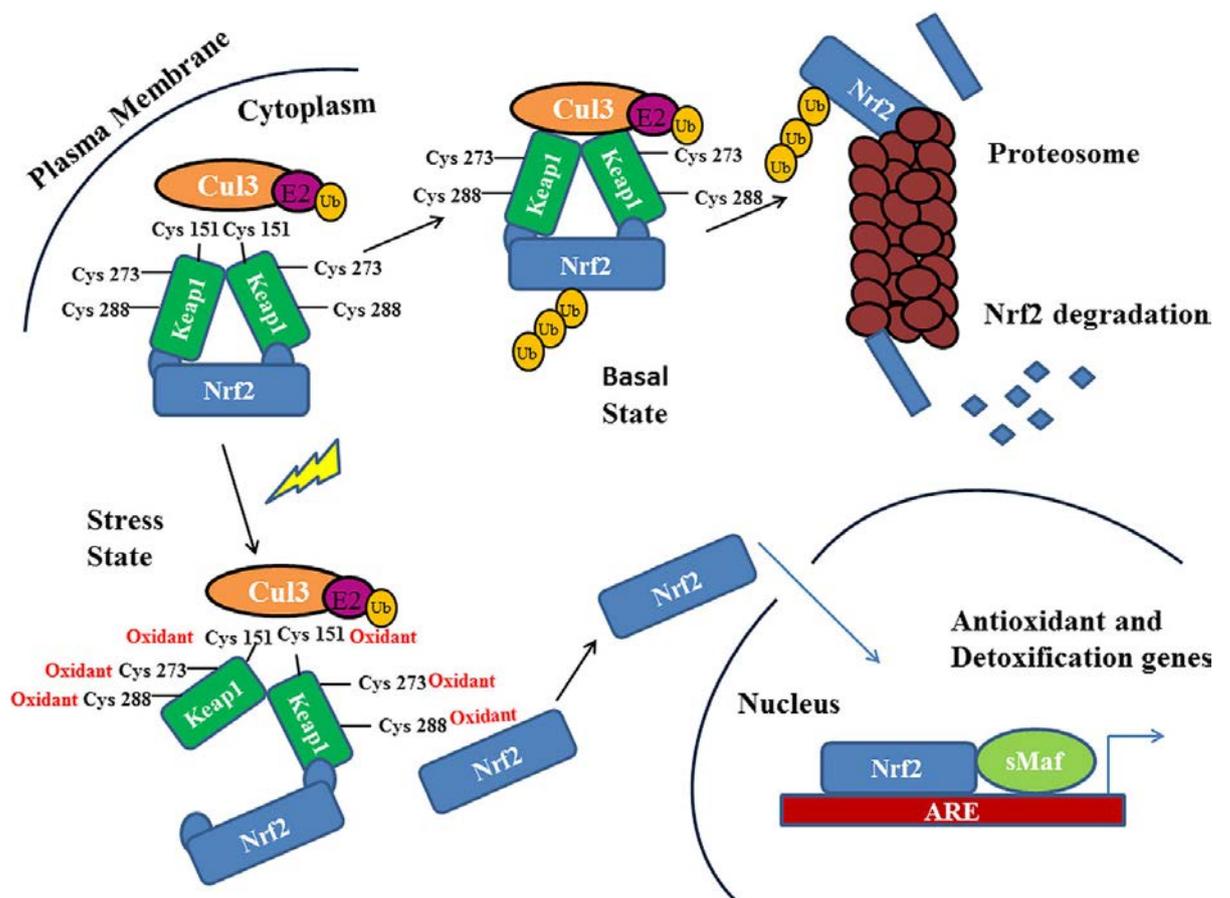

Figure 5. NRF2 is differently regulated in various situations according to the conditions. Under homeostatic conditions, NRF2 is negatively regulated and ubiquitinated through KEAP1, and degraded by the proteasome degradation pathway. Under stressed conditions, NRF2 dissociates from KEAP1, translocates into the nucleus and activates cytoprotective genes. Image taken from Deshmukh & Unni *et al* [102].

KEAP1 is a 69-kDa repressor protein that binds to NRF2 and serves as a negative regulator of NRF2. The human KEAP1 protein sequence contains 627 amino acid residues composed of five domains: i) the N-terminal region (NTR), ii) the Broad complex, Tramtrack, and Bric-a-Brac (BTB), iii) the linker intervening region (IVR), iv) the Kelch domain, and v) the C-terminal region (CTR). BTB domain is responsible for homo-dimerization and interaction with Cullin (Cul3) based ubiquitin E3 ligase complex for NRF2 ubiquitination. IVR are sensitive to oxidation and

nuclear export signal (NES) motif containing some cysteine residues. Kelch domain has six Kelch repeats (KR1-KR6) with multiple protein contact sites that mediate association of KEAP1 with NRF2 (the Kelch domain interacts with Neh2 domain of NRF2) and cytoskeleton proteins actin and/or myosin[103].

KEAP1 forms a homodimer and each dimer binds one molecule of NRF2 via its two Kelch domains, with one weak affinity binding site (DLG motif) and one high affinity binding site (ETGF motif), called “hinge-and-latch”[104]. The KEAP1-NRF2 complex is linked to a functional E3 ubiquitin ligase complex (RBX1) via an adaptor protein, Cullin3. Apart from the general model of KEAP1-CUL3 E3 ligase-mediated NRF2 ubiquitination by targeting KEAP1 cysteine residues, the three-dimensional structure of the KEAP1 Kelch domain, which is responsible for the interaction with NRF2, and the binding cavity of KEAP1 were determined by several groups in mice and humans using X-ray crystallography[105-108]. Therefore, in the pathway of KEAP1-NRF2, KEAP1 possesses dual functions: it senses the redox state using its multiple cysteine residues, and it switches the level of NRF2 ubiquitination according to the redox state. The transcription factor NRF2 acts as the executor of the pathway by inducing gene expression by binding to the cis-regulatory element ARE. While ARE determines the detailed effects of the activation of signaling only the genes with an ARE in the promoter region are involved in KEAP1-NRF2-ARE signaling.

1.3.2.3 Drug targets activating KEAP1-NRF2-ARE pathway

Activation of NRF2 signaling induces the transcriptional regulation of ARE-dependent expression of various detoxifying and antioxidant defense enzymes and proteins. Therefore, KEAP1-NRF2-ARE signaling has been an attractive target for the prevention and treatment of oxidative stress-related diseases and conditions, including cancer, neurodegenerative, cardiovascular, metabolic and inflammatory diseases [109-113]. Subsequently, a variety of KEAP1-NRF2 inhibitors were discovered.

The strategies to modulate KEAP1-NRF2-ARE pathway are multiple. Toxic chemicals, especially electrophiles that can induce oxidative stress, could activate this pathway, therefore, targeting KEAP1 cysteine residues could be an approach to indirectly inhibit KEAP1-NRF2 interaction. As many currently known ARE activators are electrophiles or can be metabolically transformed to become electrophilic, they are indirect inhibitors of KEAP1-NRF2 interaction by forming covalent adducts with the sulfhydryl groups on the cysteines in KEAP1 via oxidation or alkylation. For example, CDDO was demonstrated to covalently bind to Cys151 to inhibit the binding of Cul3 to KEAP1, which leads to the activation of NRF2 through the crystal structure of the CDDO-KEAP1 complex[114].

Compared with indirectly targeting KEAP1 cysteine residues, directly disrupting KEAP1-Cul3 protein-protein interactions seems to be more advantageous, although the specific interaction mechanism needs more structural analysis to confirm which region of KEAP1 directly associates with Cul3.

Besides, directly disrupting KEAP1-NRF2 protein-protein interaction is a novel strategy for modulating NRF2 activity [99]. Shown in Figure 6, the binding cavity in KEAP1 can be divided into five sub-pockets called P1-P5. Diverse methods have been used to explore small molecules targeting KEAP1-NRF2 protein-protein interaction. For example, high-throughput screening using a homogeneous confocal fluorescence anisotropy assay (two-dimensional fluorescence intensity distribution analysis, 2D-FIDA) was performed to discover active hits from the Evotec Lead Discovery library[115]. In addition, virtual screening methods using the receptor-ligand binding model of KEAP1-NRF2 has also been used for the drug discovery of KEAP1-NRF2 protein-protein inhibitors[116].

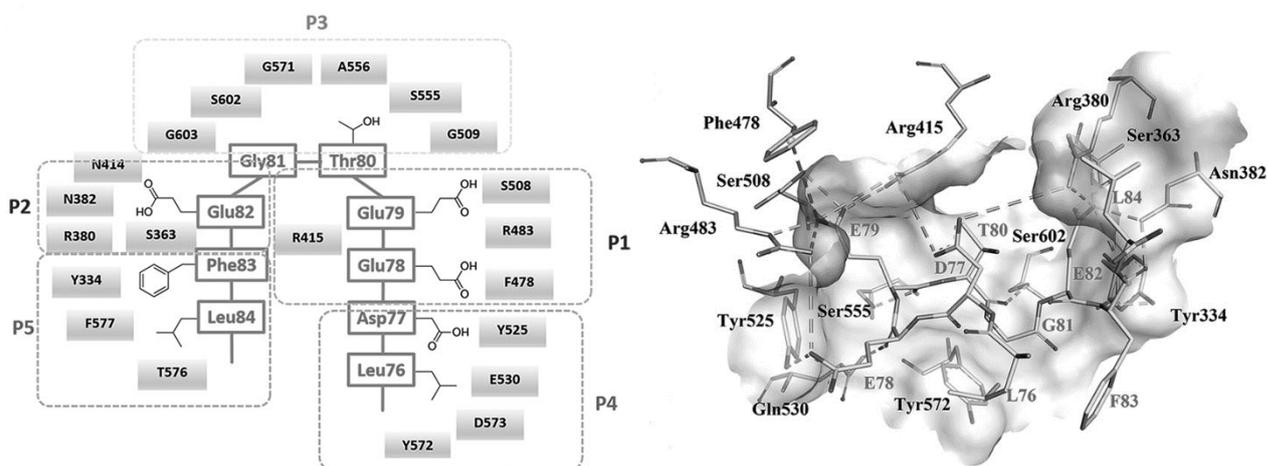

Figure 6. The KEAP1-NRF2 ETGE binding pattern. (A) Sub pocket analysis of the KEAP1 DC domain cavity. The cavity can be divided into five sub pockets: polar sub pockets P1 and P2, hydrophobic sub pockets P4 and P5, and the central sub pocket P3. (B) An interaction model of the KEAP1-NRF2 ETGE peptide. Polar interactions are represented as gray dashed lines. The NRF2 amino acid residues names are abbreviated in one capital letter, whereas the amino acid residues belonging to KEAP1 are represented in three letters. Image taken from Meng-Chen Lu, Jian-Ai Ji, Zheng-Yu Jiang, and Qi-Dong You [117].

1.4 Treatment of PTSD

1.4.1 Psychotherapy

Psychosocial interventions play a crucial role for the management of PTSD, which include trauma-focused cognitive behavior therapy (TFCBT), exposure therapy, eye movement desensitization and reprocessing (EMDR), etc. Among the diverse options, TFCBT and EMDR have the most empirical support [118]. Goncalves et al. performed a systematic review of published articles to evaluate the efficacy of virtual reality exposure therapy (VRET) in the treatment of PTSD, and the results revealed that no differences were found between VRET and

exposure therapy [119]. After the *Wenchuan* earthquake, different psychological approaches have been applied to treat earthquake survivors with PTSD in China. Wu et al. conducted a randomized controlled trial with 2,368 military rescuers for one month according to the “512 Psychological Intervention Model” and then one, two and four months later to follow up changes in PTSD symptoms, anxiety and depression based on the DSM-IV criteria. “512 PIM” was proved to be an effective psychological intervention for military rescuers in reducing symptoms of PTSD, anxiety and depression after this crisis [120]. Wang et al. developed the Chinese My Trauma Recovery approach, a web-based intervention strategy to provide mental health support for traumatized persons [121]. Short-term cognitive-behavioral therapy (CBT) group intervention represents a robust intervention for natural disaster victims [122]. A randomized waiting-list controlled pilot study was conducted at the site of the Sichuan earthquake in Beichuan County between December 2009 and March 2010, to evaluate the efficacy of Narrative Exposure Therapy (NET) as a short-term treatment for PTSD. The results suggested that NET is effective in treating post-earthquake traumatic symptoms among adult Chinese earthquake survivors [123]. In addition, Interpersonal Psychotherapy (IPT) is a 12-week structured psychotherapy developed by Klerman and Weissman in the 1980s, aiming at examining and changing current relationships and social support in order to improve mood and anxiety symptoms. Jiang et al. performed a randomized clinical trial among Sichuan earthquake survivors with IPT, a significantly higher reduction of PTSD and MDD diagnoses was found in the IPT group versus the TAU (treatment as usual) group, indicating that IPT is a promising treatment for reducing PTSD and depression [124].

1.4.2 Pharmacotherapy

Likewise psychotherapy, pharmaco-therapeutic intervention can reduce PTSD symptoms to some extent [125-127]. Different pharmacological classes with different pathogenesis have been investigated, such as selective serotonin reuptake inhibitors, α -adrenergic antagonists, anticonvulsants, mood stabilizers, antipsychotics, β -blockers, benzodiazepines, glucocorticoids, tricyclic antidepressants, and monoamine oxidase inhibitors. Nevertheless, Sertraline (Zoloft[®]) and paroxetine (Paxil[®]) are the only two drugs approved by the Food and Drug Administration (FDA) for the treatment of PTSD [128-130]. Therefore, novel effective drugs or alternative medicine are urgently needed, for instance, traditional Chinese herbs might be beneficial for the treatment of PTSD.

1.4.3 Other therapies

Other approaches, such as Yoga and meditation, defined as mind-body practice, were also useful in the treatment of PTSD [131-135]. *Taichi* and *qigong* belong to the repertoire of Traditional Chinese medicine (TCM) and represent effective approaches to treat PTSD although no study

related to *Wenchuan* earthquake has been reported [136]. Remarkably, calligraphy therapy significantly reduced hyperarousal for children among *Wenchuan* earthquake survivors [137].

1.5 Traditional Chinese Medicine

With a specific philosophical background and treatment principles, TCM emphasizes the balance of *yin* and *yang* to achieve harmony between body, mind and soul. With well-developed clinical practice and good written documentation for thousands of years, TCM is especially well suited to treat difficult and complex diseases. The success should be partly attributed to diverse medicinal plants, which have been a valuable source of therapeutic agents in the treatment of cancer, neurodegenerative diseases and malaria [138-140]. The enormous structural and chemical diversity of natural products are evolutionarily optimized for serving different biological functions [141]. In addition, the traditional knowledge on plants and well documented ethno-pharmacological information can be taken as reliable hints for further pharmacological research.

1.5.1 TCM treatment of PTSD

Acupuncture and phytotherapy are two major treatment of TCM. Acupuncture is widely used to treat trauma-related symptoms such as insomnia [142], depression [143, 144], anxiety [145, 146] and other co-morbidities [147]. Lee et al. conducted a systematic review of the effectiveness of acupuncture towards trauma spectrum response (TSR), acupuncture appeared to be effective for treating headaches, anxiety, sleep disturbances, depression and chronic pain [148]. Some trials on acupuncture were performed to treat PTSD patients among *Wenchuan* earthquake survivors. Zhang et al. compared the effectiveness with 24 cases and 67 cases with cognitive-behavior therapy and combination therapy with cognitive-behavior therapy and acupoint stimulation among *Wenchuan* earthquake patients. The total scores of IES-R, the scores of all factors and the total scores of a questionnaire among the two groups after treatment were much lower than those before treatment. The comparison of reduction in the factor scores between the two groups showed that the curative effect in the treatment group was better than in the control group [149]. Wang et al. also performed a clinical study in 138 patients with earthquake-caused PTSD using Randomized Controlled Trials (RCTs) to assess the efficacy and safety of electro-acupuncture. The cases enrolled were randomly assigned to electro-acupuncture group and paroxetine group. The electro-acupuncture group was treated by scalp electro-acupuncture on four points (*Baihui*, *Sishencong*, *Shenting*, and *Fengchi*). The results demonstrated that the total scores of Clinician-Administered PTSD Scale (CAPS), Hamilton Depression Scale (HAMD) in the treatment groups have significant efficacy, of which the electro-acupuncture group was more significant than that of paroxetine group [150].

Chinese herbs have also been demonstrated to significantly improve the symptoms of PTSD [151-154]. It's interesting that a Chinese herb formula (*Xiao-Tan-Jie-Yu-Fang*), which consists of 14 components, has been proved to be useful to treat PTSD in 245 survivors of the 2008 Sichuan earthquake in a randomized, double-blind, placebo-controlled clinical trial. PTSD-related symptoms in patients treated with this Chinese herb formula were significantly improved compared with the placebo group. The herbs can result in the improvement in somatization, obsessive-compulsive behavior, depression, anxiety, hostility, and sleep quality without serious side effects, indicating that *Xiao-Tan-Jie-Yu-Fang* represents a safe and efficient option to improve the generally poor psychological status of PTSD patients [155].

1.5.2 Free and easy wanderer

Free and easy wanderer is originated from the book of Formularies of the Bureau of People's Welfare Pharmacies in Song dynasty of China in 1078 AD. Initially, it was used for women in the treatment of irregular menstruation caused by liver stagnation (TCM language), and it is orally taken with the form of decoction. According to TCM theory, mood disorders and irregular menstruation share the same etiology, caused by liver stagnation. Therefore, FAEW is prescribed to mental patients by TCM doctors and has been widely used in clinic to remove symptoms of depression, premenstrual dysphoric disorder, climacteric syndrome in China.

Free and Easy Wanderer (Xiao-Yao-Wan, or Xiao-Yao-San, FAEW) is constituted by *Radix Bupleuri Chinensis (Chai Hu)*, *Radix Angelicae Sinensis (Dang Gui)*, *Radix Paeoniae Lactiflorae (Bai Shao)*, *Rhizoma Atractylodis Macrocephalae (Bai Zhu)*, *Sclerotium Poriae Cocos (Fu Ling)*, *Radix Glycyrrhizae Uralensis (Gan Cao)*, *Herba Menthae Haplocalycis (Bo He)* and *Rhizoma Zingiberis Officinalis Recens (Sheng Jiang)*. It has been demonstrated to reverse depressive-like behaviors in rats with type 2 diabetes[156]. FAEW reduced oxidative stress-induced hippocampus neuron apoptosis *in vitro* and change ultrastructure in rat hippocampus[157, 158]. Besides, FAEW can improve learning and memory deficit in rats induced by chronic immobilization stress[159]. Plasma-metabolite-biomarkers for the therapeutic response of FAEW in depressed patients have been identified by the NMR-based metabolomics approach[160]. Although FAEW has a good reputation in the history of Chinese medicine, the cellular and molecular modes of action are still not well-understood.

2 Aims

To understand the mechanisms of FAEW in the treatment of mental disorders, some issues should be elucidated:

(1) PTSD is known to us with loss of capabilities and dissociation symptoms, which are involved with the interruption of the normally integrative functions of consciousness, memory, identity, or perception of the environment. To understand the mechanism of PTSD, genomic analyses of clinical patients may be one potential approach to gain insight into the pathophysiology of such disorders.

(2) FAEW are poly-herbal preparations, frequently consisting of dozens to hundreds of chemical compounds, which might increase safety concerns and hamper the agreement on their clinical usage. To understand how they work in the human body, the molecular mechanisms should be clarified and possible active compounds have to be identified for further drug discovery.

Therefore, in my thesis, we started our studies by analyzing microarray-based transcriptome-wide mRNA expression profiles of PTSD patients. Based on network analyses and associated binding motifs of transcription factors in gene promoters, we hypothesized that inflammatory process may represent a major cause of PTSD. We investigated the cytotoxicity of FAEW and compared its effect with the antidepressant drug fluoxetine against inflammation by assessing the activity of NF- κ B and the protein expression of p65. Furthermore, we identified various active compounds of FAEW with molecular docking *in silico*. Finally, we compared our results with published literature and confirmed some pharmaceutical activities of the compounds.

On the other hand, we used hydrogen peroxide to induce oxidative stress in the human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines as *in vitro* cellular stress model. We examined the effect of FAEW and fluoxetine on ROS levels. To identify underlying cellular mechanisms, we performed transcriptome-wide microarray analyses. In the course of these investigations, we verified the role of KEAP1-NRF2 interaction and their downstream gene HO-1. Finally, molecular docking was performed to explore possible phytochemicals of FAEW *in silico*, which bind to the NRF2-regulator Kelch-like ECH-associated protein 1 (KEAP1).

3 Results

As mentioned previously, PTSD is widely known as a mental disorder, its etiology and pathogenic mechanism are still unknown. Therefore, we performed a systematic analysis on microarray-based transcriptome-wide mRNA expression profiling of patients with posttraumatic stress syndrome to understand the possible mechanisms of PTSD and identify some potential targets for the treatment of PTSD.

3.1 A systematic analysis on microarray-based transcriptome-wide mRNA expression profiling of patients with posttraumatic stress syndrome

3.1.1 Canonical pathways analysis

To identify the common pathways related to PTSD, the top 10 canonical pathway of each dataset was displayed by IPA analyses (**Figure 7**). In general, a variety of pathways were demonstrated to be involved. In dataset 1 and 2, the gene profiles were involved with cancer and tumor pathways. In dataset 3, cellular pathways “change of immune system” and “monocyte among the immune system” were significantly involved. In dataset 4, the main pathways occurred in mitochondria, such as “mitochondrial dysfunction” and “oxidative phosphorylation”.

3.1.2 Diseases and functions analysis of the datasets

As well as canonical pathways analysis, the diseases and functions were classified as well. Top ten relevant diseases and functions to these dysregulated genes were shown in **Figure 8**. Cellular dysfunctions, inflammation and free radical scavenging were highly involved. The dysregulated genes were also associated with diverse diseases, such as cardiovascular diseases, cancer, organismal development and neurological diseases.

3.1.3 Networks analysis of the datasets

Finally, network analyses were performed to investigate the protein-protein relationship within the dysregulated genes (**Figure 9**). Among the four datasets, NF- κ B played a central role in the networks of dysregulated genes in four datasets, implying that the inflammation might be a mechanism of PTSD.

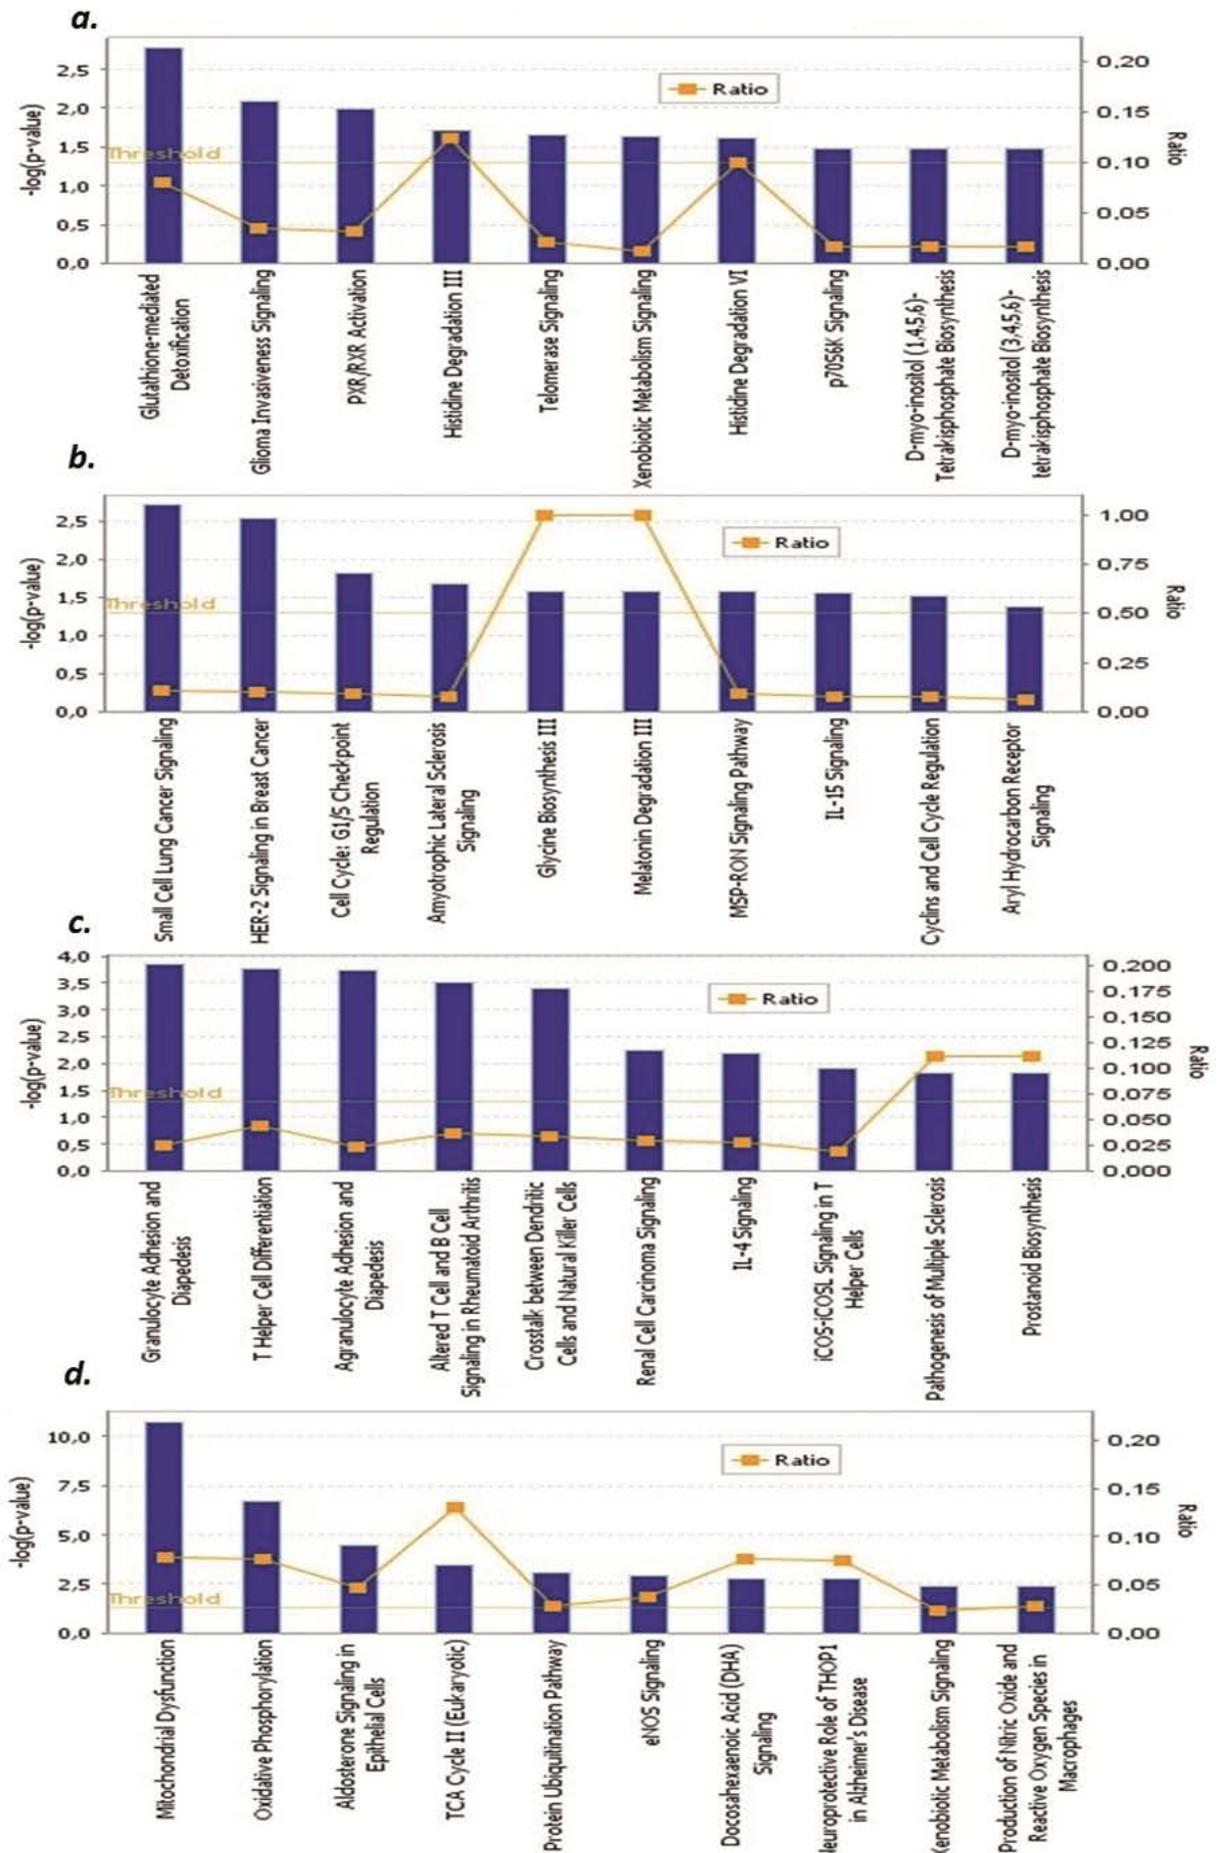

Figure 7. The top 10 canonical pathways significantly affected by PTSD. *a)* Blood-based gene-expression according to [161]; *b)* Peripheral blood mononuclear cell gene expression profiles according to [162]; *c)* Monocyte gene expression profiles according to [163]; *d)* Post mortem brain biopsy gene expression profiles according to [164].

Continuous lines show direct interactions, dotted lines indirect interactions. *a)* Blood-based gene-expression according to [161]; *b)* Peripheral blood mononuclear cell gene expression profiles according to [162]; *c)* Monocyte gene expression profiles according to [163]; *d)* Post mortem brain biopsy gene expression profiles according to [164]

3.1.4 Analysis of binding motifs for transcription factors in gene promoters

Integrative gene promoter analyses were performed to investigate common binding motifs for transcription factors in the promoter sequences of dysregulated genes among the datasets. **Table 2** shows the top ranked transcription factors. Among them was the NF- κ B binding motif with a z-score of -4.39. **Figure 10** shows detailed information of the NF- κ B.

Table 2. The most pronounced gene promoter binding motifs depending on the integrative analysis of Galaxy /Cistrome.

3.1.5 Summary

In the present investigation of our studies, the dysregulated genes of PTSD patients were involved with a wide array of pathways, diseases and functions, such as psychological or physiological diseases, which might be taken as a general hint for common pathogenic factors between PTSD and metabolic syndrome, cardiovascular diseases, cancer, as well as psychological diseases, *e.g.* depression, suicidality and anxiety [109, 165, 166], implying that a holistic way to investigate PTSD might be one approach to achieve multiple-targets. In addition, network analyses revealed that NF- κ B was involved in both blood cells and central nervous system. Furthermore, the participation of NF- κ B has also been demonstrated in the promoter binding motif search analysis, suggesting that NF- κ B may be an important immunological component of inflammatory processes in PTSD.

As well as inflammation, it is also worthwhile to notice that oxidative stress-related pathways, such as mitochondrial dysfunction and oxidative phosphorylation, have also been demonstrated to be involved with PTSD, which could be suggested by the diseases and functions analysis, and pathway analysis. Although the specific pathway was not indicated in the network analysis, the role of oxidative stress and its signal pathway could also be one point for the following studies.

3.2 NF- κ B was inhibited by the Chinese herbal remedy *Free and Easy Wanderer*

The previous chapter gave an overview of PTSD with clinical datasets. Inflammatory process has been demonstrated to participate in PTSD, suggested by the pathway analysis, diseases and functions analysis. The network analysis stressed the important role of NF- κ B. In addition, promoter binding motif search of genes revealed that NF- κ B was among the most important transcription factors. These findings showed a strong signal that NF- κ B could be a target in the treatment of PTSD. Therefore, in this part, we aimed to validate the effect of FAEW with the link between the therapeutic effect of FAEW on PTSD, and NF- κ B as relevant underlying mechanism.

3.2.1 Cytotoxicity of FAEW and fluoxetine

To identify the role of NF- κ B in the acting model of FAEW, firstly, resazurin assays in HEK293 cells were performed to investigate, whether or not FAEW reveals cytotoxic effects. As shown in **Figure 11**, FAEW was indeed not cytotoxic at concentrations up to 2000 μ g/ml. For comparison, fluoxetine was non-toxic up to 6 μ M and inhibited HEK293 cells at higher concentrations.

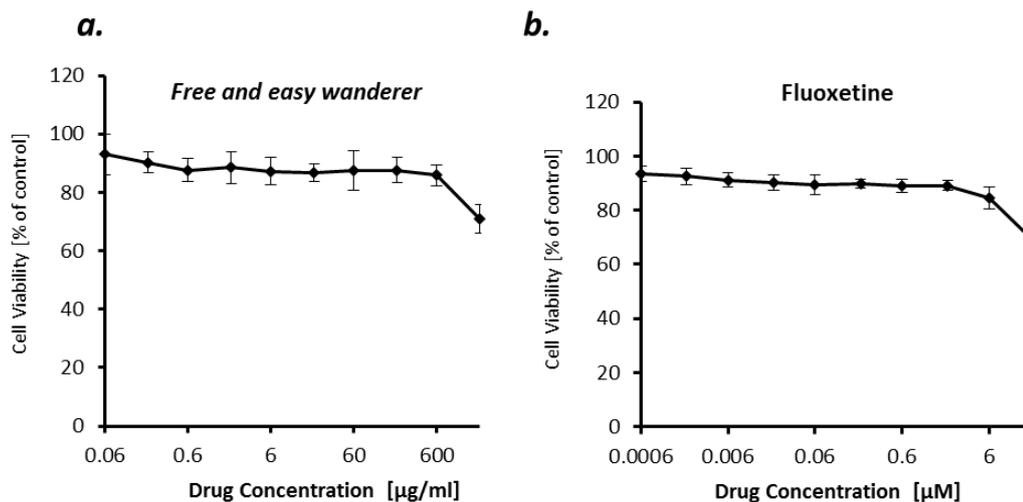

Figure 11. Cytotoxicity of FAEW and fluoxetine as determined by the resazurin assay. Shown are mean values \pm SD of three independent experiments.

3.2.2 Inhibition of NF- κ B activity by FAEW and fluoxetine

To investigate whether FAEW affects PTSD through NF- κ B-mediated inflammatory effects, NF- κ B reporter cell assays were performed. As shown in **Figure 12**, FAEW inhibited NF- κ B activity in a dose-dependent manner. In addition, the inhibitory effect strengthened in a time-dependent manner from 24 to 72 h, reaching the similar inhibitory level caused by MG-132. Fluoxetine revealed the same trend as FAEW.

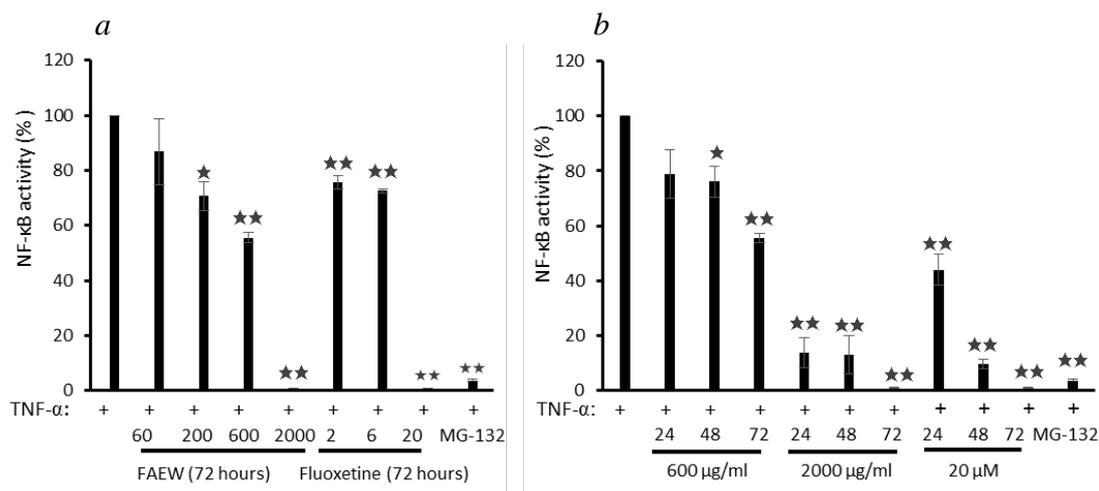

Figure 12. Inhibition of NF-κB activity by FAEW and fluoxetine in HEK293 reporter cells. (a) Concentration kinetics and (b) time kinetics shown are mean values \pm SD of three independent experiments. * $p < 0.05$, ** $p < 0.01$. The inhibition effects of FAEW and fluoxetine towards NF-κB activity were calculated by comparison with untreated TNF- α induction group.

3.2.3 Inhibition of p65 protein expression by FAEW and fluoxetine

To further confirm the inhibition of NF-κB, western blot assays were performed to investigate the role of FAEW on p65 protein expression in T98G brain cells. According to the cytotoxic assays in **Figure 13**, three non-cytotoxic concentrations (200, 40, 8 μg/ml) were selected. As shown in **Figures 13a** and **Figures 13c**, with treatment for 24 h, both FAEW and fluoxetine inhibited p65 expression in a dose-dependent manner. Fixed concentrations of 200 μg/ml FAEW or 20 μM fluoxetine inhibited p65 expression in a time-dependent manner from 24 to 72 h (**Figures 13b** and **Figures 13d**).

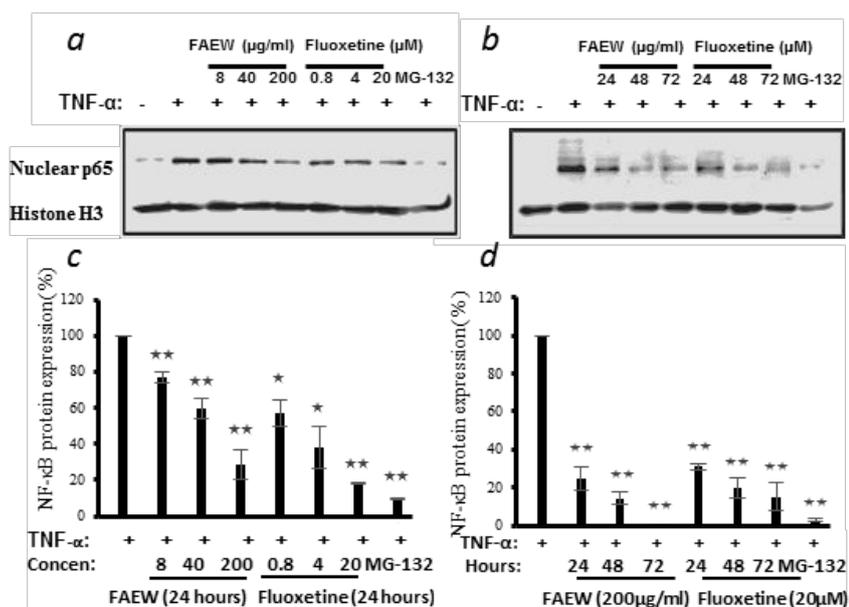

Figure 13. Inhibition of p65 expression by FAEW and fluoxetine in T98G brain cells. (a) Concentration kinetics and (b) time kinetics. Histone was used as loading control. (c) and (d) show inhibition effects of FAEW and fluoxetine towards p65 protein expression were compared with TNF- α group after using the control group without TNF- α for the quantification of western blots shown in (a) and (b), respectively. Shown are mean values \pm SD of three independent experiments. * $p < 0.05$, ** $p < 0.01$.

3.2.4 Structures of 10 phytochemicals from FAEW

Ten compounds were isolated from the herb mixture of FAEW, and their structures were identified by HPLC-NMR and MS, as shown in **Figure 14**.

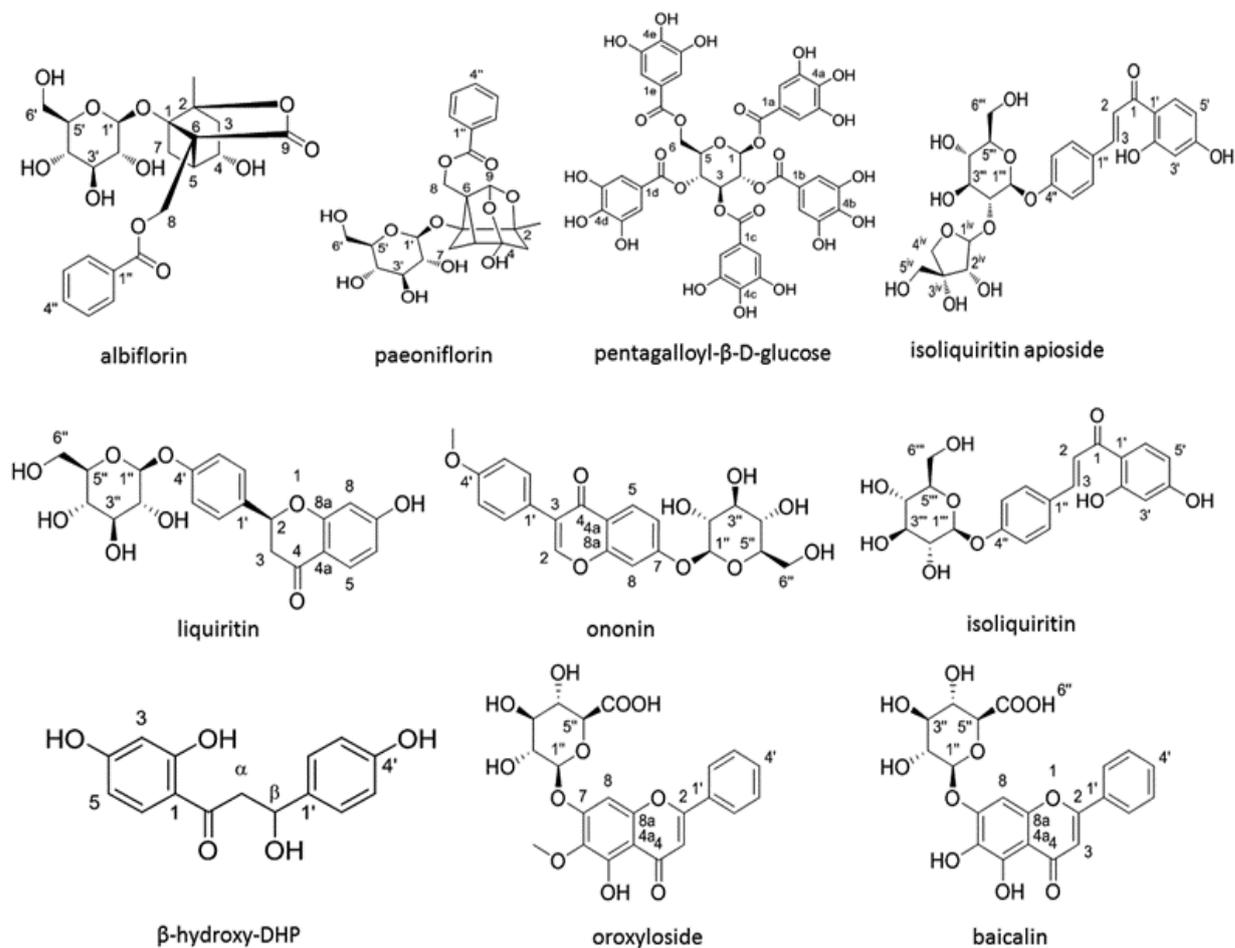

Figure 14. The structures of 10 compounds isolated from FAEW

3.2.5 *In silico* molecular docking of compounds from FAEW binding to the proteins of the NF- κ B pathway

In order to explore possible interactions of compounds known to be in FAEW with the proteins of the NF- κ B pathway, *in silico* molecular docking analysis were performed with 10 compounds (shown in **Figure 14**) in the remedy to I κ K-NEMO, I κ K and p65-RelA. As shown in **Table 3** and **Table 4**, paeoniflorin and ononin bound to I κ K and p65-RelA with low binding energies, which were comparable to the binding of MG-132. In addition, isoliquiritin apioside, albiflorin, baicalin, isoliquiritin, liquiritin and oroxyloside mainly bound to p65-RelA through DNA and ATP binding sites (**Figures 15** and **Figure 16**). The control fluoxetine (S) bound to p65-RelA with high affinity.

Table 3. Binding energies of molecular docking of chemical compounds of FAEW to proteins of the NF- κ B pathway.

Ligand	I κ K-NEMO		I κ K		p65-Rel A	
	Lowest binding energy (kcal/mol)	pKi (μ M)	Lowest binding energy (kcal/mol)	pKi (μ M)	Lowest binding energy (kcal/mol)	pKi (nM)

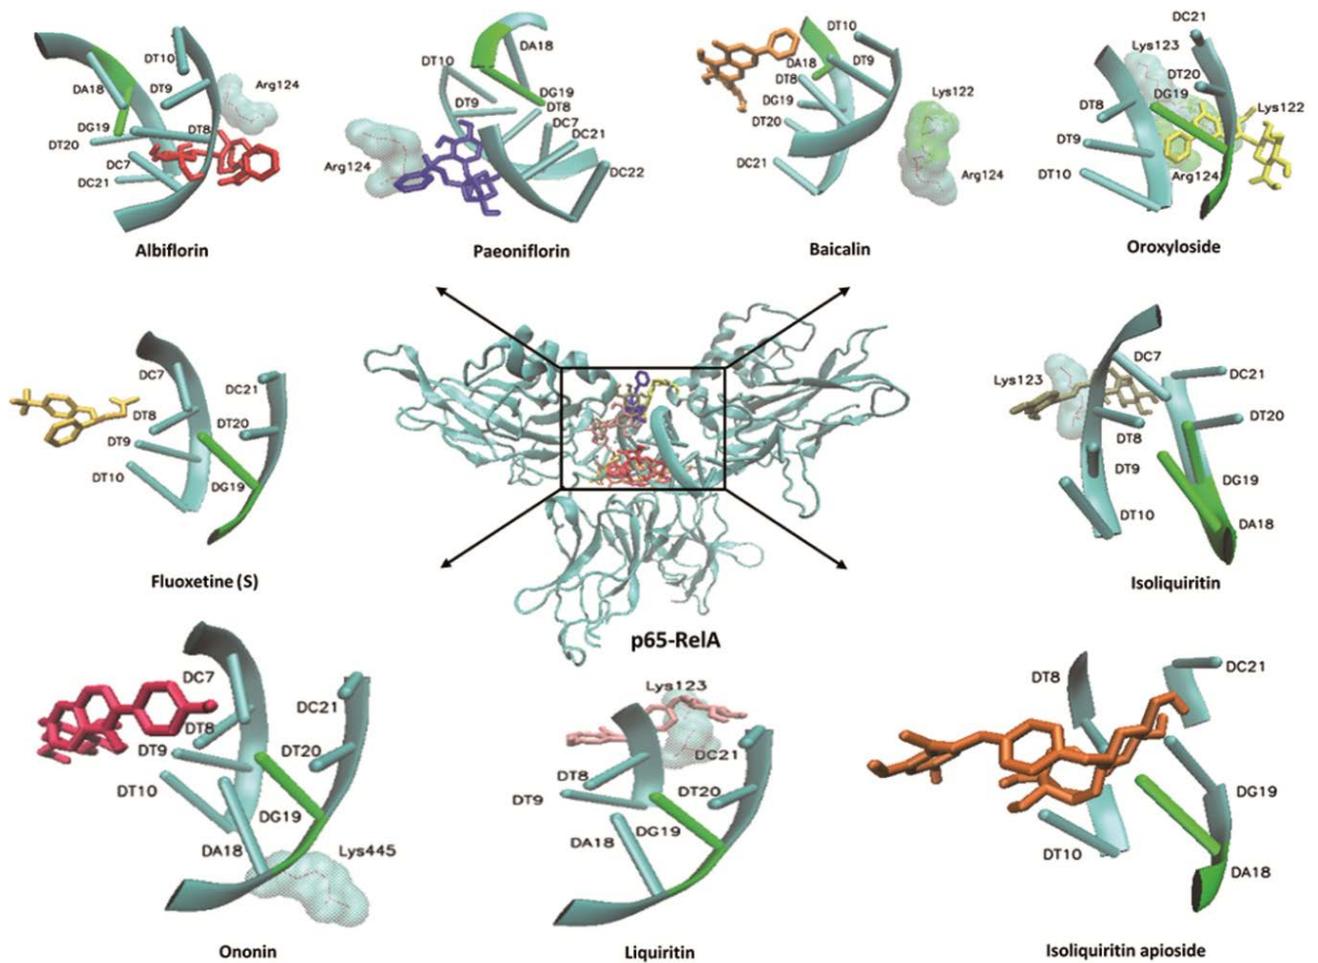

Figure 16. Visualization of molecular docking of chemical compounds of FAEW to p65.

3.2.6 Literature review on the pharmacological activity and anti-inflammation of the compounds from FAEW

To further characterize the therapeutic potential of the candidate compounds investigated by molecular docking, we performed literature review of the current research on the isolated compounds of FAEW. As shown in **Table 5**, paeoniflorin, albiflorin and baicalin were reported to *in vitro* act against inflammation and oxidative stress, and to be effective *in vivo* against depression, and Parkinson's disease. Furthermore, clinical trials were carried out among herbal formulae in inflammation-related diseases, such as Japanese traditional recipe *Shakuyakukanzoto*, and the Chinese herb formula *Xiongshao capsule*. *In vivo* studies on isoliquiritin and liquiritin showed their activities against depression and cognitive-related diseases, for instance, Parkinson's disease. As shown in **Table 6**, paeoniflorin, baicalin and liquiritin have been demonstrated to reduce inflammatory processes related to numerous diseases *in vitro* and *in vivo* through inhibiting NF- κ B, which implies their role as constituents of FAEW acting against inflammatory reactions related to PTSD.

Table 5. Literature review on the pharmacological activity of the compounds from FAEW

Compounds	pharmacological activity		
	<i>In vitro</i>	<i>In vivo</i>	Clinical studies
Paeoniflorin	Anti-inflammation and oxidative stress [167]; neuroprotection [168]; apoptosis [169]	Parkinson's disease [170]; depression [171]; neuropathic pain [172]; non-alcoholic steatohepatitis [173]	Rheumatoid arthritis [174]; muscle cramps and abdominal pains [175]; restenosis after percutaneous coronary intervention [176]
Albiflorin	Oxidative stress [177]; neuroprotection [178]	Anti-depression [179]; Parkinson's disease [180]; neuropathic pain [172, 181]	Muscle cramps and abdominal pains [175]
Baicalin	Inflammation[182]; apoptosis[183]; oxidative stress[184]	Alcoholic liver injury[185]; depression /anxiety [55]; renal damage [56]; memory impairment[57]	Ulcerative colitis[186]
Liquiritin	Neuroprotection [187]	Cognitive deficits [188]; Parkinson's disease [189]; depression [190]; focal cerebral ischemia [191]	Melisma [192]
β -hydroxy-DHP	Apoptosis [193]		
Isoliquiritin apioside	Anti-genotoxic [194]		
Isoliquiritin	Anti-allergic activity [194]	Depression [195]; antifungal activity [196]	Depression [197]
Oroxyloside		Colitis [198]; inflammation-related diseases [199]	

Table 6. Literature review of the effect of chemical constituents of FAEW against NF- κ B.

Compounds	pharmacological activity on NF- κ B	
	<i>In vitro</i>	<i>In vivo</i>
Paeoniflorin	Parkinson's disease [200]; immunomodulation [201]; Alzheimer's disease [202]; apoptosis [167]; morphine tolerance [203]; anti-inflammation and immunomodulation [204]; sepsis [205]; obesity [206]; cardiac remodeling [207]	Renal function [208]; non-alcoholic steatohepatitis [173]; cardiac dysfunction [209]; vascular dementia [210]; Alzheimer's Disease [211]; arthritis [212]; hepatitis [213]; colitis [214]; learning dysfunction and brain damage [215]; lung injury [216]
Baicalin	Myofibroblast differentiation [217]; atherosclerosis [218]; haemophilus parasuis infection [219]; mastitis [220]; apoptosis [221]	Asthma [222]; periodontitis [223]; allergic diseases [224]; arthritis [225]; brain edema [226]; lung injury [227]; liver injury [228]; ischemic stroke [229]; cerebral ischemia [230]
Isoliquiritin	Inflammatory responses [231]	
Liquiritin	Endothelial dysfunction [232]	Myocardial fibrosis [233]; acute Lung Injury [234]
Oroxyloside		Colitis [198]

3.2.7 Summary

In this part, we observed that FAEW was not cytotoxic with a wide range, it was indeed not cytotoxic in HEK293 cells at concentrations up to 2000 μ g/ml. FAEW significantly inhibited NF- κ B activity in a dose-dependent manner and time-dependent manner from 24 to 72 h, reaching the similar inhibitory level caused by MG-132 at 72 h. Its effect in inhibiting NF- κ B has also been demonstrated in the protein level in T98G brain cells. Hence, FAEW might exert anti-anxiety effects through inhibiting NF- κ B-mediated inflammatory process.

In the investigation of this section, 10 compounds were identified in the extract of FAEW, they were baicalin, β -hydroxy-DHP, isoliquiritin, isoliquiritin apioside, liquiritin, ononin, oroxyloside, albiflorin, paeoniflorin, and pentagalloyl- β -D-glucose. To identify the active compounds, we performed molecular docking to investigate the binding modes of the identified FAEW compounds with NF- κ B pathway related proteins

Among a panel of 10 compounds, paeoniflorin, isoliquiritin apioside and ononin exerted high affinity to I κ K and p65-RelA. Baicalin, isoliquiritin, liquiritin and oroxyloside strongly bound to p65-RelA. Paeoniflorin, albiflorin, baicalin, isoliquiritin and liquiritin were reported to be active against depression and Parkinson's disease in *in vivo* studies and clinical trials, and paeoniflorin, baicalin and liquiritin were reported to inhibit NF- κ B *in vitro* and *in vivo*. These data demonstrated that FAEW is constituted by a wide array of diverse anti-depressant natural drugs with strong anti-inflammatory activity.

3.3 The Chinese herb formula *Free and Easy Wanderer* ameliorates oxidative stress through KEAP1-NRF2/HO-1 pathway

3.3.1 Cytotoxicity of FAEW and fluoxetine

As the first step, we performed resazurin assays in human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines to investigate whether FAEW reveals cytotoxic effects or not. As expected, FAEW was indeed not cytotoxic towards T98G cells at concentrations up to 300 $\mu\text{g/ml}$ (**Figure 17A1**). For comparison, fluoxetine was non-toxic up to 3.1 $\mu\text{g/ml}$ (10 μM) and inhibited T98G cells at higher concentrations (**Figure 17A2**). However, both FAEW and fluoxetine have no cytotoxicity towards SH-SY5Y cell, even at higher concentrations (**Figure 17B1**, **Figure 17B2**).

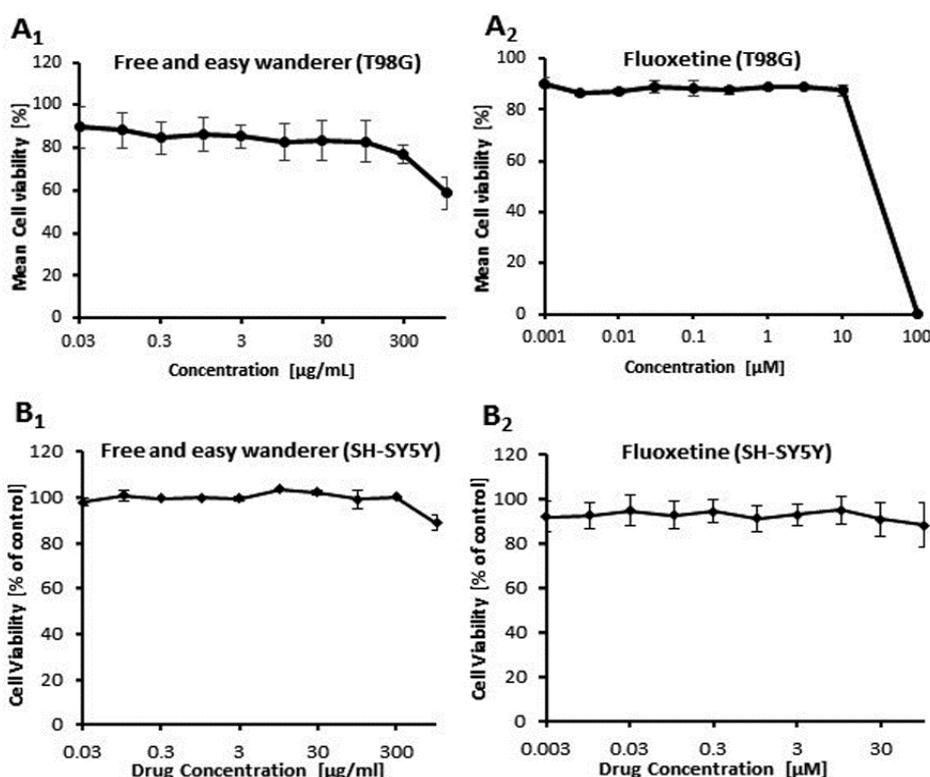

Figure 17. Cytotoxicity of FAEW (1) and fluoxetine (2) as determined by the resazurin assay in the human glioblastoma T98G (A) and human neuroblastoma SH-SY5Y (B) cells. Shown are mean values \pm SD of three independent experiments.

3.3.2 Inhibition of ROS generation by FAEW and fluoxetine

We selected several non-cytotoxic concentrations of FAEW and fluoxetine, and performed flow cytometric experiments to investigate ROS levels. Firstly, we used H_2O_2 to induce oxidative stress *in vitro*. As shown in **Figure 18A1** and **Figure 18B1**, FAEW strongly reduced the levels of ROS induced by H_2O_2 and the levels of ROS in untreated T98G and SH-SY5Y cells, indicating that FAEW diminished exogenous H_2O_2 -induced ROS and also protected against endogenous ROS. Fluoxetine showed the same effect as FAEW shown in **Figure 18A2** and **Figure 18B2**.

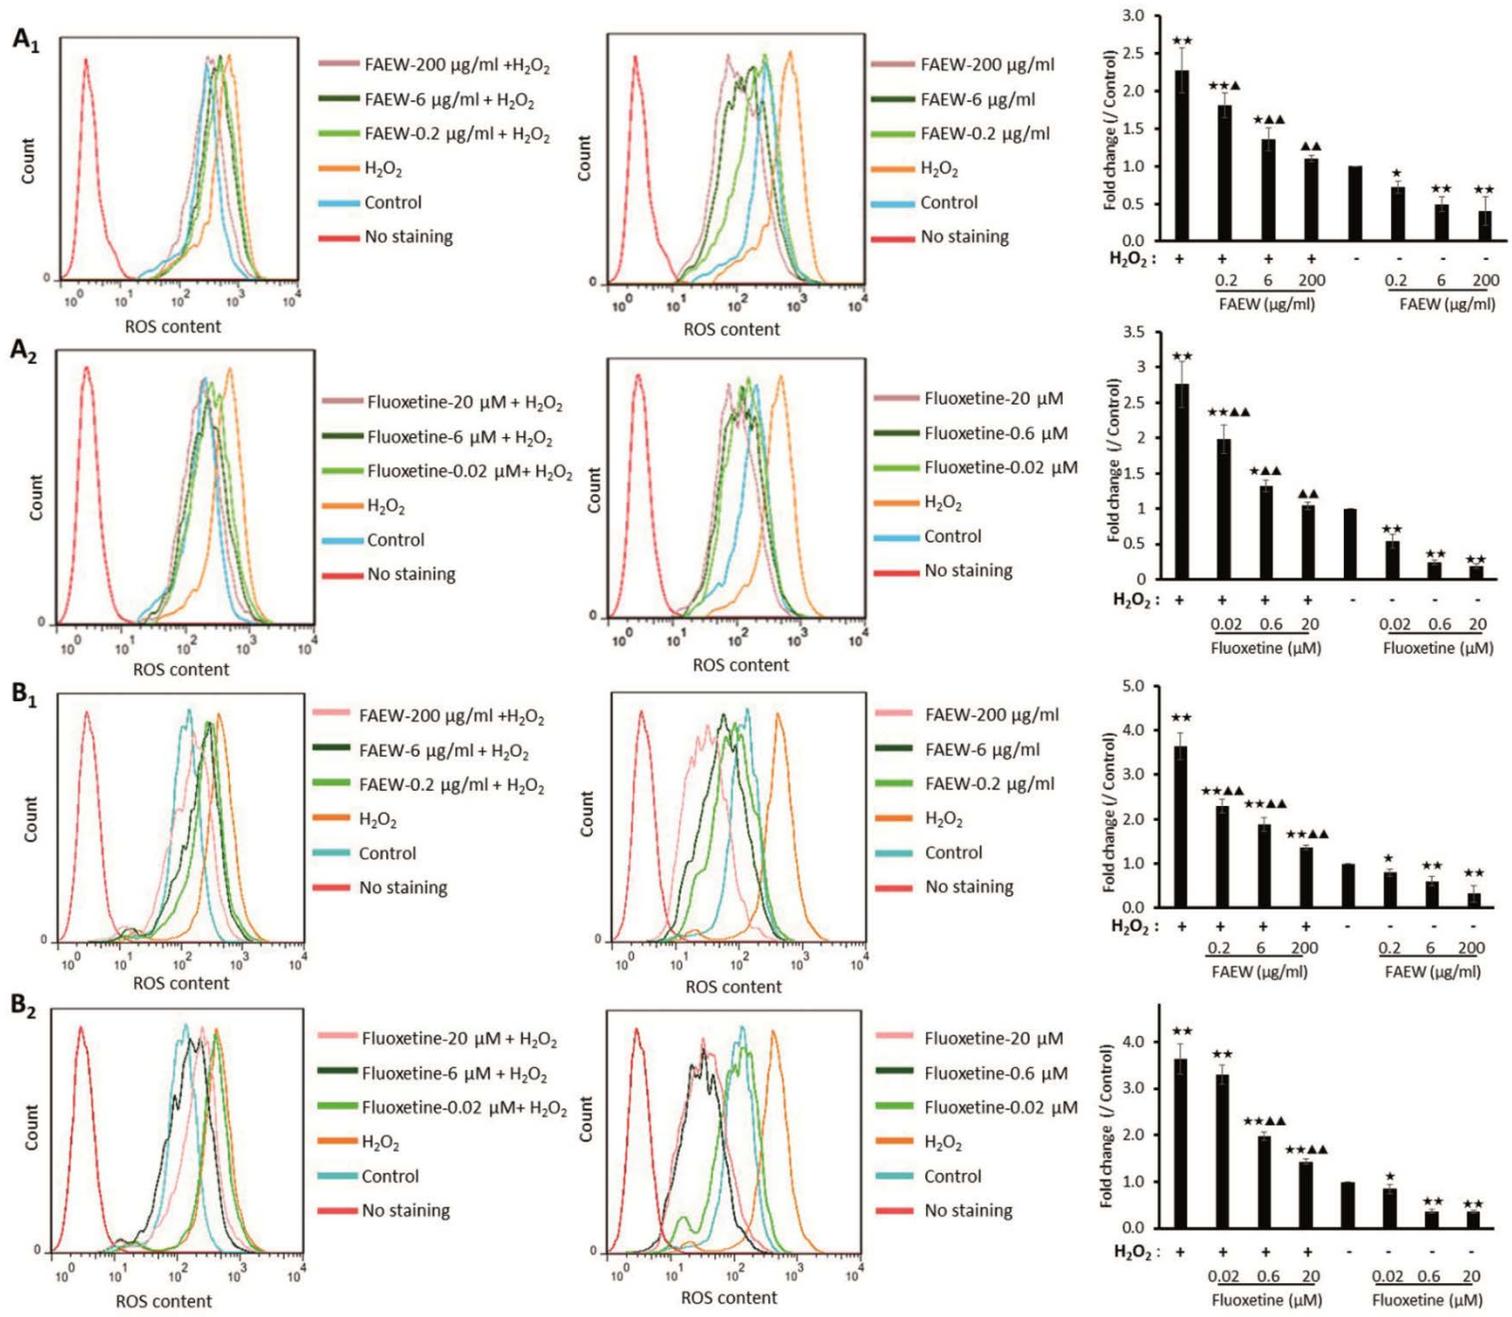

Figure 18. Inhibition of reactive oxygen species by FAEW (1) or fluoxetine (2) in the human glioblastoma T98G (A) and human neuroblastoma SH-SY5Y (B) cells. Shown are mean values \pm SD of three independent experiments. * $p < 0.05$, ** $p < 0.01$, compared with control; \blacktriangle $p < 0.05$, $\blacktriangle\blacktriangle$ $p < 0.01$, compared with H₂O₂.

3.3.3 Gene expression profiling caused by FAEW and fluoxetine

Gene expression profiling was performed to obtain deeper insight into the mechanisms of FAEW and fluoxetine against oxidative stress. Therefore, total RNA was extracted to perform transcriptome-wide microarray analyses, after human glioblastoma T98G cells were treated with FAEW or fluoxetine for 48 h, and oxidative stress was induced with H₂O₂ for 6 h.

All data obtained by microarray analyses were subjected to pathway analysis. The deregulated genes were correlated with several molecular and cellular functions and pathways. As shown in **Figure 19A** and **Figure 19B**, NRF2-mediated oxidative stress was the top-ranked pathway upon FAEW treatment. Furthermore, an upstream regulator analysis was performed with IPA to identify transcriptional regulators, kinases, or enzymes that may be responsible for gene expression changes in T98G cells after treatment. **Table 7** shows the upstream transcriptional factors predicted by IPA to be affected by FAEW and fluoxetine. Remarkably, NFE2L2 (alias NRF2) (underlined) was found to be a commonly activated transcription regulator by both FAEW and fluoxetine, implying that NRF2-mediated stress response may be involved with the mechanisms of the two drugs. **Table 8** displays the targeted genes downstream of NRF2 upon different treatment models. Most interestingly, *HMOX1* (alias *HO-1*) was commonly targeted by FAEW and fluoxetine with or without oxidative stress. Six deregulated downstream genes of NRF2, including *HMOX1* were quantified by real-time RT-PCR to technically validate the microarray results. KEAP1 was identified as a cytoplasmic NRF2-interacting protein that negatively regulates NRF2 activity, but recent studies revealed that alternative mechanisms of NRF2 activation that do not rely on KEAP1[235]. Therefore, we also investigated the transcriptional levels of NRF2 and KEAP1. The correlation coefficients (R-values) between mRNA expression values determined by microarray hybridization and real-time RT-PCR were in the range of 0.83 to 0.97 for each compound (Pearson correlation test), indicating a high degree of concordance between the data obtained from the two different methods (**Table 9**). The levels of KEAP1 and NRF2 were not affected, which excluded the transcription regulation and autoregulation, and suggested the possibility of participation of KEAP1-NRF2 protein-protein interaction. **Figure 19C** shows the deregulated genes controlled by NRF2 upon treatment by FAEW and fluoxetine, respectively.

Table 7. Most pronounced upstream transcription factors for deregulated genes upon different treatments.

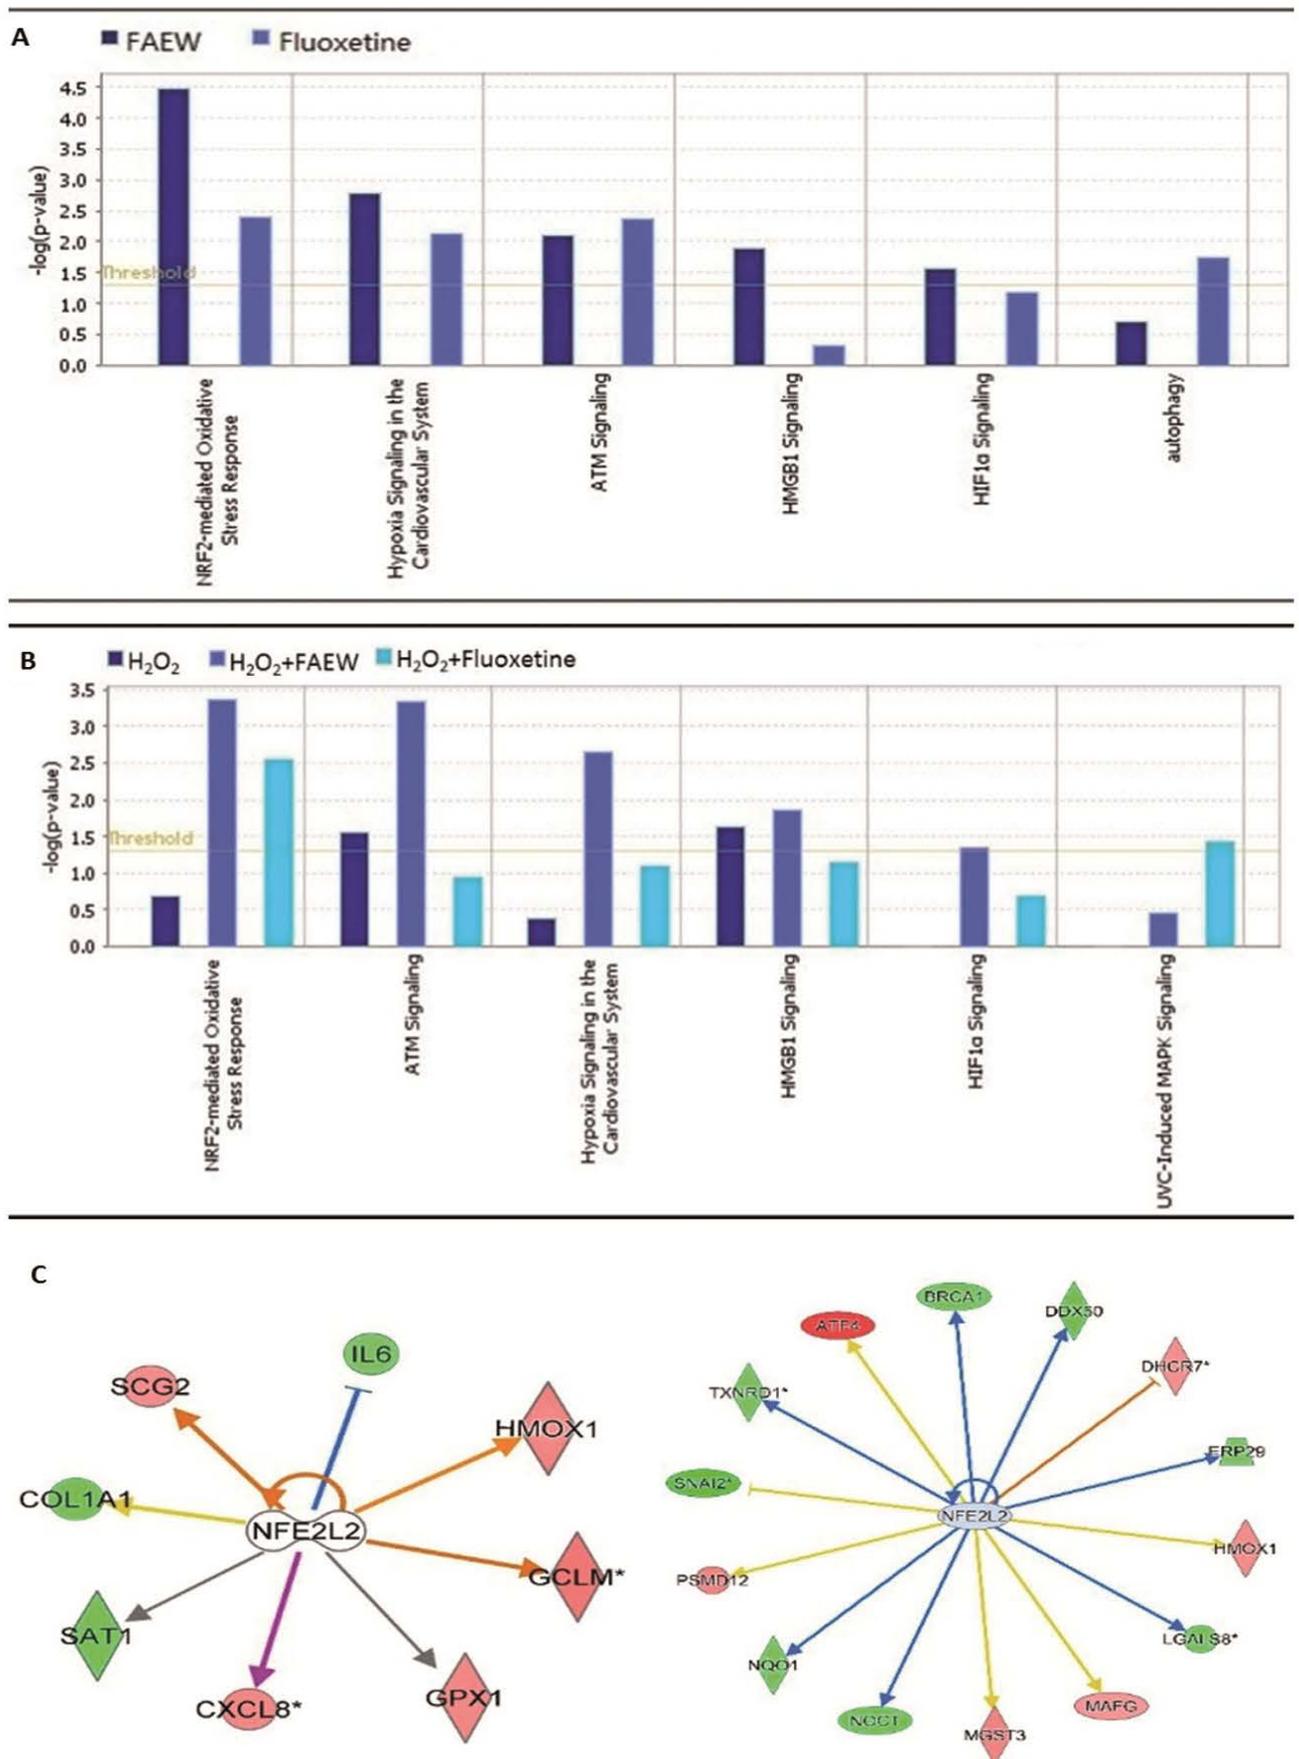

Figure 19. Gene expression profiling of T98G cells upon treatment of FAEW or fluoxetine. (A and B). Pathway analyses: Top cellular pathways affected by FAEW and fluoxetine examined by mRNA microarray hybridization. (A) shows the comparison between FAEW and fluoxetine. (B) shows the comparison between H₂O₂, H₂O₂ and FAEW, H₂O₂ and fluoxetine. P-values were calculated using right-tailed Fisher's exact test. (C) Deregulated genes under the influence of the common upstream regulator NFE2L2 (NRF2) inhibited by FAEW (left) and fluoxetine (right).

3.3.4 Inhibition of KEAP1-NRF2 interaction by FAEW and fluoxetine

To further investigate the protective mechanism of FAEW against oxidative stress, we performed western blotting with NRF2 pathway-related proteins to clarify the participation of the NRF2-HO-1 pathway. As shown in **Figure 20A**, **Figure 20B**, **Figure 20C** and **Figure 20D**, FAEW and fluoxetine both promoted nuclear NRF2 translocation. The expression levels of NRF2 in the nucleus were significantly increased with or without stressed conditions induced by H₂O₂. Meanwhile, the levels of total HO-1 also significantly increased, which confirmed the prediction by microarray analysis. H₂O₂ also triggered NRF2 translocation at short times, *i.e.* 10 min and 6 h. The effects diminished with longer times of H₂O₂-induced stress, *i.e.* 12 to 24 h. The HO-1 levels significantly increased after stress induction for 6 h, the trend lasted for 24 h. While, there is no significant change for the protein expression of catalase (CAT) upon the different treatment. Interestingly, in parallel with the translocation of NRF2 from the cytoplasm, cytosolic KEAP1 levels decreased, indicating a correlation between KEAP1 and NRF2. **Figure 20E** and **Figure 20F** display the dose-response relation of nuclear NRF2, cytoplasmic NRF2, cytoplasmic KEAP1 and HO-1 upon treatment with FAEW or fluoxetine among human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines, respectively.

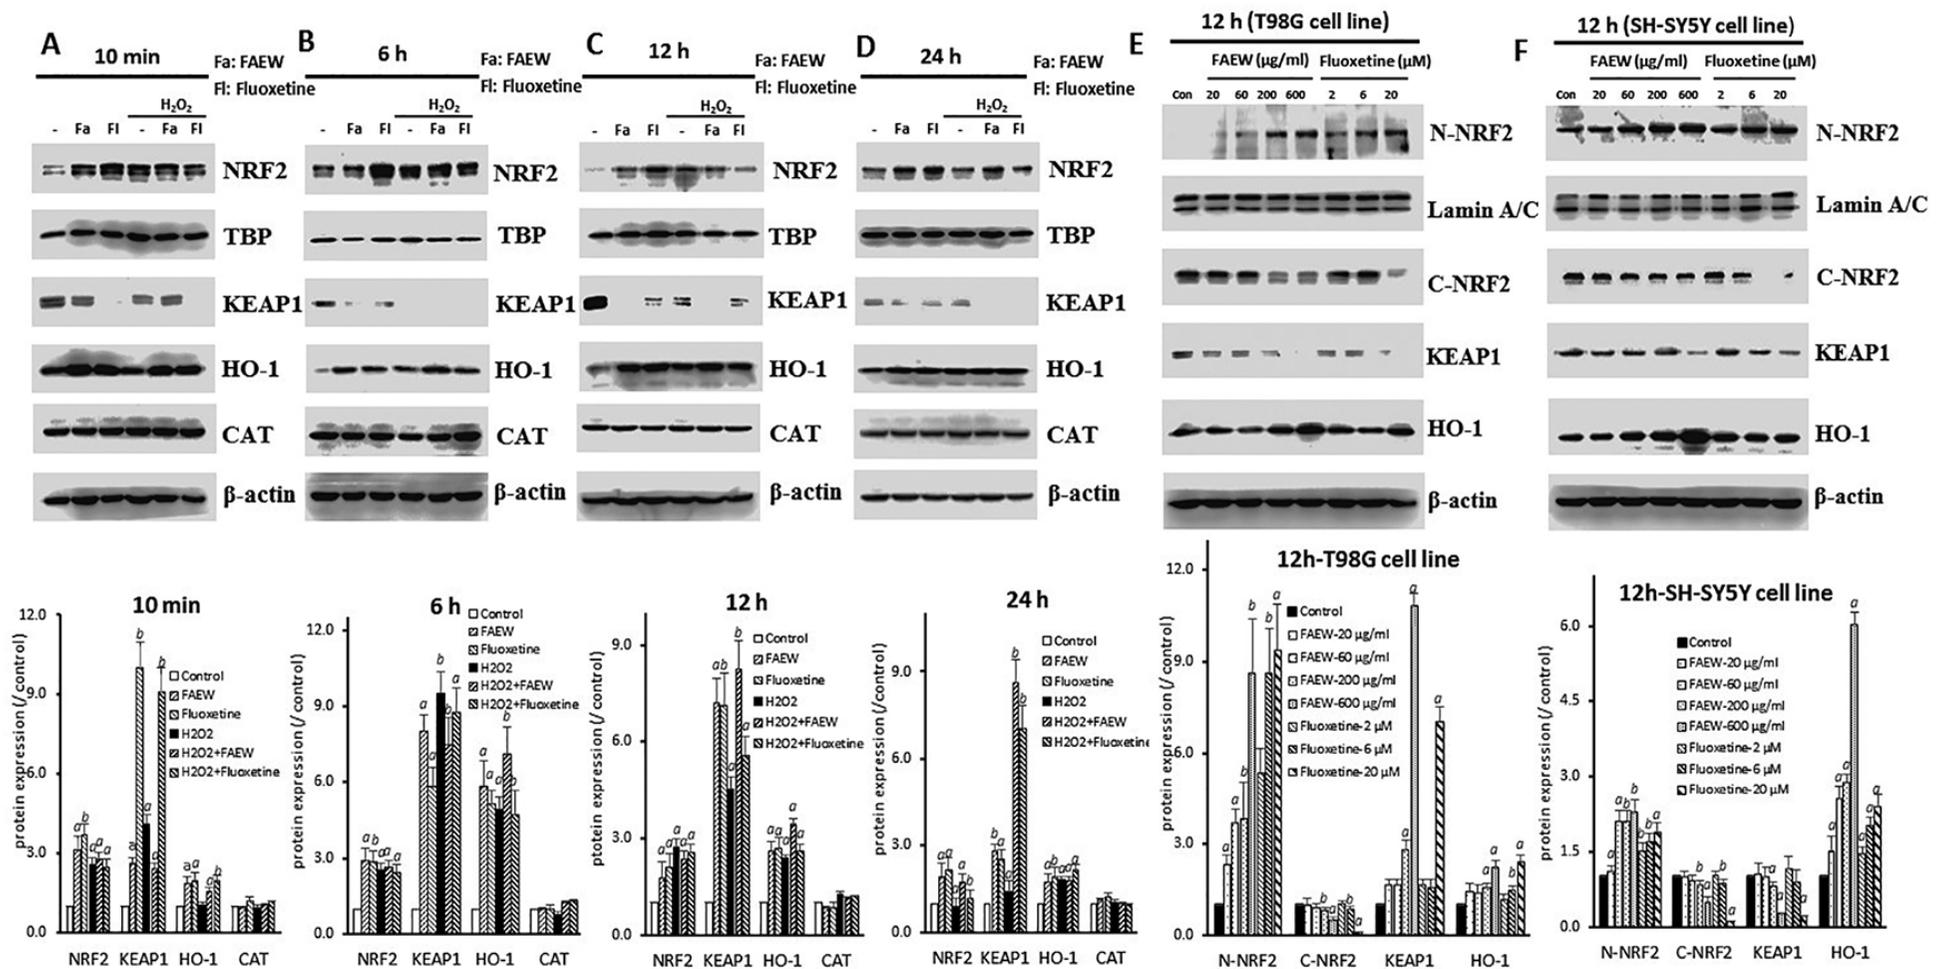

Figure 20. NRF2, HO-1, CAT and KEAP1 protein expression affected by FAEW or fluoxetine in human glioblastoma T98G cells and human neuroblastoma SH-SY5Y cells. A, B, C and D show NRF2, HO-1, CAT and KEAP1 protein expression affected by FAEW or fluoxetine in human glioblastoma T98G cells with different induction times for H₂O₂ (A, 10 min; B, 6 h; C, 12 h; D, 24 h, respectively). TBP was used as loading control for nuclear proteins and β-actin was used as loading control for cytoplasmic proteins. E and F show cytoplasmic and nuclear NRF2, cytoplasmic KEAP1 and total HO-1 protein expression in human glioblastoma T98G (E) and human neuroblastoma SH-SY5Y (F) cells with different concentrations of FAEW and fluoxetine for 12 h. Lamin A/C was used as loading control for nuclear protein, β-actin was used as loading control for cytoplasmic protein. Shown are mean values ± SD of three independent experiments. ^a *p* < 0.01, ^b *p* < 0.05.

3.3.5 *In silico* molecular docking of compounds from FAEW to KEAP1

Initially, we performed molecular dockings to predict binding energies of 10 compounds from FAEW, the antidepressant control drug fluoxetine and another control drug, IQK, which is a KEAP1-NRF2 interaction inhibitor. Except for isoliquiritin apioside and pentagalloyl- β -D-glucose, the other compounds were predicted to exhibit higher binding affinities than fluoxetine (-5.01 kcal/mol for fluoxetine (S)), especially baicalin (-7.45 kcal/mol), oroxyloside (-7.89 kcal/mol) and liquiritin (-6.86 kcal/mol). **Figure 21** shows the predicted binding sites of the compounds to KEAP1.

Table 10. *In silico* molecular docking of chemical compounds isolated from FAEW to KEAP1.

Ligands	Binding energy (kcal/mol)	Ki (μ M)	Residues forming H-bonds	Residues involved in hydrophobic interactions
Baicalin	-7.45 \pm 0.04	3.47 \pm 0.23	Asn382, Asn414, Arg415, Ser555, Ser602	Tyr334, Arg380, Ile461, Gly462, Phe478, Ser508, Ala556, Tyr572
Ononin	-5.57 \pm 0.08	83.58 \pm 10.40	Ser602	Tyr334, Ser363, Gly364, Arg415, Ile416, Gly462, Ala556, Tyr572, Phe577, Gly603
Isoliquiritin	-5.87 \pm 0.19	51.78 \pm 15.65	Asn382, Ser602	Tyr334, Gly364, Arg415, Ile416, Gly462, Gly509, Ala510, Ala556, Phe577, Gly603

3.3.6 Anti-oxidative effect of the compounds isolated from FAEW extract

Among the compounds isolated from FAEW, paeoniflorin, albiflorin, baicalin, and isoliquiritin have been reported against oxidative stress *in vitro*, they are active against apoptosis, neurotoxicity and oxidative injury, *In vivo* experiments revealed their effect in quite many diseases, such as chronic obstructive pulmonary disease, diabetics, colitis. In addition, liquiritin, isoliquiritin apioside were active towards oxidative stress-induced genotoxicity, as shown in **Table 11**.

Table 11. Literature review of the effect of chemical constituents of FAEW against oxidative stress

Compounds	<i>In vitro</i>	<i>In vivo</i>
Paeonifloirin	Neurotoxicity[200]; apoptosis[167, 236, 237]; oxidative injury[238]; cell damage[239]; osteoblast cytotoxicity[240]	Cholestasis[241], chronic obstructive pulmonary disease[242]
Albiflorin	Neurotoxicity[177, 180], oxidative stress[177]	Diabetics[243]
Baicalin	Oxidative injury[244, 245]; apoptosis[246]	Colitis[247]; <i>Haemophilus parasuis</i> infection[219]; vascular inflammation[248]; neurotoxicity[249]; skin fibroblast[250]
Isoliquiritin	Neurotoxicity[251]	Oxidative stress-induced genotoxicity[194]
Isoliquiritin apioside		Oxidative stress-induced genotoxicity[194]
Liquiritin		Myocardial fibrosis[233], depression[252], lung epithelial cell injury[253], cognitive deficits[254], endothelial dysfunction[232]

3.3.7 Summary

In the investigation of this section, we employed exogenous H₂O₂ for ROS induction in human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines as the cellular stress model to investigate the effect of FAEW and fluoxetine on oxidative stress. Our results indicated that ROS levels significantly increased upon H₂O₂ treatment. Both FAEW and fluoxetine effectively diminished ROS generated by H₂O₂. Furthermore, they also significantly reduced the levels of endogenous ROS in untreated cells, suggesting their capability against oxidative stress by removing both endogenous and exogenous ROS. Furthermore, the nuclear levels of NRF2 increased upon the induction by H₂O₂. In parallel, cytoplasmic KEAP1 levels decreased accordingly, which confirmed the interaction of KEAP1 and NRF2 under stress situations shown in previous studies [255]. Compared with the H₂O₂-induced dissociation of NRF2 from KEAP1, both FAEW and fluoxetine alone resulted in the translocation of NRF2 from cytoplasm to the nucleus, as the levels of cytoplasmic NRF2 decreased with the occurrence of the elevation of nuclear NRF2 levels. Besides, the level of nuclear NRF2 increased in a KEAP1-dependent manner, and the antioxidant response element HO-1 significantly elevated at transcriptional and translational levels upon treatment of FAEW or fluoxetine. In addition, the transcriptional levels of *NRF2* and *KEAP1* were not affected by the treatment of FAEW or fluoxetine. This can be taken as another hint for the capability of FAEW and fluoxetine to inhibit the KEAP1-NRF2 protein-protein interaction.

In this study, we proved that FAEW exerted strong activity against oxidative stress in human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines. The herbal mixture treatment reduced both endogenous and exogenous ROS, strongly promoted NRF2 translocation to the

nucleus in a KEAP1-dependent manner and, hence, HO-1 levels increased. The underlying mechanism for FAEW against oxidative stress may be related to multiple compounds, which bound to KEAP1-NRF2 protein-protein interaction sites and lead to the release of NRF2 from KEAP1 and NRF2 translocation to the nucleus, implying FAEW might be active against psychiatric disorders by reducing oxidative stress. Furthermore, oroxyloside, baicalin, liquiritin, paeoniflorin, albiflorin etc. revealed high affinities to KEAP1, which might be the effective substances of FAEW against oxidative stress. *In vivo* experiments revealed their effect in quite many diseases, such as chronic obstructive pulmonary disease, diabetics, colitis. These data demonstrated that FAEW is constituted by a wide array of diverse anti-depressant natural compounds with activity against oxidative stress.

4 Discussion

4.1 Identification of NF- κ B as determinant of posttraumatic stress disorder and its inhibition by the Chinese herbal remedy *Free and Easy Wanderer*

4.1.1 Identification of NF- κ B as determinant of PTSD

Increasing evidence indicated an involvement of immune system in fear- and anxiety-based disorders. Recent studies suggested that inflammation is associated with increased basal ganglia glutamate in patients in depression [110]. Furthermore, inflammasome signaling affects anxiety- and depressive-like behavior and gut microbiome composition, and suggesting that the gut microbiota-inflammasome-brain axis could be novel therapeutic targets for psychiatric disorders [111]. In our studies, network analyses revealed that NF- κ B was activated in both the peripheral and central nervous system. In addition, promoter binding motif search of genes revealed that NF- κ B was among the most important transcription factors. These results indicated that NF- κ B may be an important immunological component of inflammatory processes in PTSD. Therefore, we hypothesized a link between the therapeutic effect of FAEW on PTSD, and NF- κ B as relevant underlying mechanism.

4.1.2 Inhibition of NF- κ B by FAEW and Structure Activity relationship of FAEW compounds

In our studies, we observed that FAEW was not cytotoxic with a wide range and showed a dose and time-dependent inhibition of NF- κ B activity in HEK293 cells as well as of protein expression of NF- κ B in T98G brain cells. Among the panel of 10 compounds, paeoniflorin, isoliquiritin apioside and ononin exerted high affinity to I κ K and p65-RelA. Baicalin, isoliquiritin, liquiritin and oroxyloside strongly bound to p65-RelA. For example, paeoniflorin bound with I κ K and p65 through multiple hydrogen bonds involving the OH groups of its glucose moiety. The hemiacetal OH-group in the core (position 5) and the 3'- and 4'-OH of paeoniflorin are predicted to bind to I κ K residues Thr23, Met 96 and Glu 97, respectively. In the interaction of the same compound with p65, the 5-OH and the glucose OH groups in positions 3', 4', and 6' bound to the p65 residues DT9, DC22, DT8 and DC21, respectively. Besides, p65 residue DG 19 donates a hydrogen bond to the benzoate carbonyl of paeoniflorin. The same type of interactions for the other compounds from FAEW can be applied to explain their activities towards NF- κ B, such as ononin, isoliquiritin. Furthermore, paeoniflorin, albiflorin, baicalin, isoliquiritin and liquiritin were reported to be active against depression and Parkinson's disease in *in vivo* studies and clinical studies, and paeoniflorin, baicalin and liquiritin were demonstrated to inhibit NF- κ B *in vitro* and *in vivo*. These data suggested that FAEW is constituted by various natural compounds with high activity against inflammation. Importantly, some compounds have been indeed demonstrated to pass the blood-

brain barrier and reach brain tissue, e.g. albiflorin, paeoniflorin, liquiritin, which might explain the effect of FAEW in the central nervous system [256]. In addition, it is also quite interesting to observe that some compounds were used to treat colitis *in vivo* and in clinic studies, which might imply their participation in the balance of the gut- microbiota-inflammasome-brain axis [186, 198].

4.1.3 Summary and conclusion

In our studies, we observed that, with diverse active compounds, FAEW has high activity against inflammation by inhibiting NF- κ B, which were comparable to the antidepressant drug, fluoxetine. It is not cytotoxic and approachable for the treatment of inflammation-related diseases. The literature review provided us some hints for future studies, to confirm and investigate the activity of different components of FAEW. To conclude the above results and discussions, *Free and easy wanderer* is active against inflammation by inhibiting NF- κ B, the mechanism might be related to the multiple natural products binding to I κ K and p65 through hydrogen bonds, which might also be the mechanism in the treatment of mental disorders.

4.2 The Chinese herb formula *Free and Easy Wanderer* ameliorates oxidative stress through KEAP1-NRF2/HO-1 pathway

4.2.1 Reactive oxygen species removal by *Free and Easy Wanderer*

Oxidative stress occurs if molecular defense systems fail to counteract oxidation caused by endogenous processes such as the mitochondrial breakdown of glucose for energy supply or by exogenous xenobiotic chemicals, air pollution and diet. It reflects an imbalance of a biological system's ability to detoxify reactive intermediates or repair resulting damage. Due to the essential role for physical well-being, longevity and survival, oxidative stress is involved in a variety of diseases, including diabetes, cardiovascular illnesses and neurodegenerative conditions. ROS are byproducts of aerobic metabolism, including the superoxide anion (O₂⁻), hydrogen peroxide (H₂O₂), and hydroxyl radicals (OH⁻). All of them have inherent chemical properties that confer reactivity to different biological targets. Rats under stress conditions exhibited greater anxiety-like behavior and increased ROS levels than corresponding control animals, and vice versa, induction of ROS generation resulted in anxiety-like behavior [93]. These observations suggest a causative link between ROS and mental disorders.

In our studies, we therefore, employed exogenous H₂O₂ for ROS induction in human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines as the cellular stress model to investigate the effect of FAEW and fluoxetine upon oxidative stress. Our results indicated that ROS levels significantly increased upon H₂O₂ treatment. Both FAEW and fluoxetine effectively diminished ROS generated by H₂O₂. Furthermore, they also significantly reduced the levels of endogenous

ROS in untreated cells, suggesting their capability against oxidative stress by removing both endogenous and exogenous ROS.

4.2.2 NRF2-KEAP1-ARE pathway activation upon oxidative stress

NRF2 is composed of six functional domains known as NRF2-ECH homologies (Neh) and designated as Neh1-6, respectively [97]. Under normal physiological conditions, NRF2 is sequestered in the cytosol and maintained at a low level through KEAP1-dependent ubiquitination and proteasome degradation. Human KEAP1 are highly reactive towards ROS and electrophiles and are believed to be involved in redox sensing with the existence of seven active cysteine residues (i.e., Cys151, Cys257, Cys273, Cys288, Cys297, Cys434, and Cys613) [109, 165, 166]. In the presence of oxidative stress, such as ROS or electrophilic chemicals, the cysteine residues of KEAP1 are covalently modified. These chemical modifications result in conformational changes in KEAP1 that relieve NRF2 from KEAP1-directed degradation. NRF2 translocates to the nucleus and activates ARE-dependent gene expression of a series of anti-oxidative and cytoprotective proteins, such as HO-1[98]. In our studies, the nuclear levels of NRF2 increased upon the induction by H₂O₂. In parallel, cytoplasmic KEAP1 levels decreased accordingly, which confirmed the interaction of KEAP1 and NRF2 under stressed situations shown in previous studies [100, 101].

4.2.3 KEAP1-NRF2-ARE pathway activation by *Free and Easy Wanderer*

KEAP1-NRF2-ARE pathway represents one of the most important cellular defense mechanisms against oxidative stress and xenobiotic damage. Activation of NRF2 signaling induces the transcriptional regulation of ARE-dependent expression of various detoxifying and antioxidant defense enzymes and proteins. KEAP1-NRF2-ARE signaling has become an attractive target for the prevention and treatment of oxidative stress-related diseases and conditions including cancer, neurodegenerative, cardiovascular, metabolic and inflammatory diseases. Recent studies indicated that NRF2 may play an essential role in the central nervous system. NRF2-dependent persistent oxidative stress resulted in stress-induced vulnerability to depression in rats [96]. KEAP1-NRF2 signaling is involved in depression in a mice model [257], implying that interruption the KEAP1-NRF2 protein-protein interaction might be a potential therapeutic approach against depression.

Subsequently, a variety of KEAP1-NRF2 protein-protein interaction inhibitors were discovered, and the disruption of KEAP1-NRF2 protein-protein interactions became a novel approach for drug discovery of antioxidant agents[99]. In my studies, compared with the H₂O₂-induced dissociation of NRF2 from KEAP1, both FAEW and fluoxetine alone resulted in the translocation of NRF2 from cytoplasm to the nucleus, as the levels of cytoplasmic NRF2 decreased with the occurrence of the elevation of nuclear NRF2 levels. Besides, the level of nuclear NRF2 increased

in a KEAP1-dependent manner, and the antioxidant response element HO-1 significantly elevated at transcriptional and translational levels upon treatment of FAEW or fluoxetine. In addition, the transcriptional levels of NRF2 and KEAP1 were not affected by the treatment of FAEW or fluoxetine. This can be taken as another hint for the capability of FAEW and fluoxetine to inhibit the KEAP1-NRF2 protein-protein interaction. Furthermore, we performed molecular docking to investigate the binding modes of the identified FAEW compounds with KEAP1. Indeed, oroxyloside, baicalin, liquiritin, paeoniflorin, albiflorin etc. revealed strong affinities to KEAP1, which might be the effective substances of FAEW against oxidative stress. Importantly, some compounds have been indeed demonstrated to pass the blood-brain barrier and to reach the brain tissue (*e.g.* albiflorin, paeoniflorin and liquiritin), which may further explain the effect of FAEW on the central nervous system [256].

4.2.4 Summary and conclusion

In this study, we proved that FAEW exerted high activity against oxidative stress in human glioblastoma T98G and human neuroblastoma SH-SY5Y cell lines. The herbal mixture reduced both endogenous and exogenous ROS, strongly promoted NRF2 translocation to the nucleus in a KEAP1-dependent manner and, hence, caused elevated HO-1 levels. The underlying mechanism for FAEW against oxidative stress may be related to multiple compounds, which bound to KEAP1-NRF2 protein-protein interaction sites and lead to the release of NRF2 from KEAP1 and NRF2 translocation to the nucleus, implying FAEW might be clinically effective in the treatment of mental disorders through reducing oxidative stress.

4.3 Limitations and recommendations for future work

Free and Easy Wanderer is called *Xiao-Yao-Wan*, or *Xiao-Yao-San* in China, depending on the dosage forms it was made. On the market, FAEW is commonly sold by pills or powder, with the names *Xiao-Yao-Wan* and *Xiao-Yao-San*, respectively. It is constituted by *Radix Bupleuri Chinensis* (*Chai Hu*), *Radix Angelicae Sinensis* (*Dang Gui*), *Radix Paeoniae Lactiflorae* (*Bai Shao*), *Rhizoma Atractylodis Macrocephalae* (*Bai Zhu*), *Sclerotium Poriae Cocos* (*Fu Ling*), *Radix Glycyrrhizae Uralensis* (*Gan Cao*), *Herba Menthae Haplocalycis* (*Bo He*) and *Rhizoma Zingiberis Officinalis Recens* (*Sheng Jiang*).

FAEW contains doses of natural compounds, the ingredients that can be identified quite depend on the extraction method and isolation techniques. In my experiment, we used *Xiao-Yao-Wan* with the form of pills and ten compounds were identified by using HPLC/MS techniques. Although the quantity control of FAEW in Chinese Pharmacopeia only mentioned two ingredients paeoniflorin and albiflorin, other approaches have been demonstrated to improve the identification and quality control for FAEW. A room-temperature super-extraction system (RTSES) was

applied to extract the major active components of FAEW and enhance their psychopharmacological effect by improving the regulation of blood glucose and increasing the insulin sensitivity in reserpine-induced anxiety and depression as well as activating cerebral 5-HT_{1A} receptors [258]. Besides, capillary electrophoresis fingerprints was established to optimize applied to the background electrolyte in capillary zone electrophoresis and can be served as a novel reference to identify and control the quality of FAEW[259]. Therefore, other methods can be applied and compared to explore the active compounds in future studies.

In my studies, we performed biological experiments with the extract of FAEW *in vitro*. It demonstrated that FAEW is active against inflammation and oxidative stress, through inhibiting NF κ B and activating KEAP1-NRF2/HO-1 pathway, respectively, which might be one part of the future *in vivo* and clinical studies. Other activities of FAEW have been also reported. For example, FAEW improved depressive-like behavior in rats through modulation of β -arrestin 2-mediated pathways in hippocampus[260]. Another study indicated that FAEW treatment can effectively improve depressive-like behaviors in rats through inhibition of locus coeruleus-norepinephrine neurons activity[261]. FAEW has also been demonstrated to act against corticosterone-induced stress injury via upregulating glucocorticoid receptor reaction element transcriptional activity, and improve the anxiety-like behaviors of rats induced by chronic immobilization stress with the involvement of the JNK signaling pathway in the hippocampus [262, 263]. In addition, the endogenous metabolites in depressed patients treated with TCM formula FAEW were dynamically analyzed using urinary (1)H NMR-based metabolomics and the data suggested the involvement of energy metabolism, gut microbes, tryptophan metabolism and taurine metabolism[264]. A similar research on the plasma-metabolite-biomarkers for the therapeutic response in depressed patients by the traditional Chinese medicine formula FAEW confirmed the results[160]. The following experiment demonstrated that FAEW could effectively adjust the gut dysbacteriosis in functional dyspepsia[265].

The limitations of my study can provide some hints for future studies. The conclusion that FAEW might be effective in the treatment of mental disorders through the activity against inflammation and oxidative stress is performed *in vitro*. An integrated investigations on the activity of FAEW *in vivo* and in clinic could be part of future work. FAEW is a poly-herb with multiple compounds, in our studies, only ten compounds were isolated due to the limitations of isolation methods. On one hand, standardized fingerprint methods could be applied to improve the quality and identify the active compounds of FAEW. On the other hand, future studies, should, therefore, focus on the individual roles of the identified compounds from FAEW and their binding modes to the proteins involved. Finally, more *in vivo* and clinical studies should be performed to validate the multiple targets of FAEW with respect to mental disorders such as PTSD and to explore the underlying mechanisms.

5 Material and Methods

5.1 Gene expression profiling and network analysis of PTSD patients

Gene expression profiling from PTSD patients were searched from Pubmed, GEO dataset and Google Scholar database. Among all the results, only four were related to our analysis with data available [161-164]. Among the datasets we have chosen for our study, three were derived from blood samples[161-163], and one was originated from *post mortem* collected brain tissue biopsies[164]. To allow comparisons between the four datasets, consistent fold-change ratios were calculated between the control and PTSD groups. Gene symbols (or IDs) and fold-change values were uploaded into the Ingenuity Pathway Analysis (IPA) software[266] to determine canonical signal transduction pathways, gene functions and signaling networks predicted by dysregulated gene expressions.

5.2 Binding motif search for transcription profiles in gene promoter sequences

Transcription factor binding site analyses were performed by the Cistrome analysis software [267]. Briefly, regulated genes were input and BED formats, a tab-delimited text file defining data lines displayed in an annotation track, were retrieved with an upstream setting (promoter region) at 2 kb[268]. SeqPos motif analyses were used to screen for enriched motifs in given regions (<http://cistrome.org>). Using SeqPos, we scanned all the motifs not only in Transfac, JASPAR, UniPROBE (pbm), hPDI database, but also attempted to identify de novo motifs using MDscan algorithm. The output of genes was ranked by $-\log_{10}$ (p-value).

5.3 Chemicals and equipment

FAEW and fluoxetine

The FAEW extract was prepared from commercial pills (Xiaoyao wan) purchased from Wanxi Pharmaceutical Company (Henan Province, China). Five bottles of FAEW pills were mixed and dissolved in H₂O : MeOH : DCM in a ratio of 1 : 4 : 5 for three days. A rotary evaporator was used to remove the solvents and the final extracts were stored at -20°C. Fluoxetine was purchased from Sigma-Aldrich (Steinheim, Germany).

5.4 Cell cultures

5.4.1 T98G cell line

Human glioblastoma T98G cell line was obtained from the German Cancer Research Center (DKFZ, Heidelberg, Germany). The original source of these two cell lines is the American Type

Culture Collection (ATCC). Human glioblastoma T98G cell line was cultivated under standard conditions (37°C, 5% CO₂) in DMEM medium supplemented with 10% fetal bovine serum (Life Technologies, Darmstadt, Germany), 1% penicillin/streptomycin (Life Technologies, Darmstadt, Germany). Cells were passaged twice a week. All experiments were performed with logarithmically growing cells.

5.4.2 HEK 293 cell line

HEK293 cells stably expressing the HEK-Blue-Null vector and secreted embryonic alkaline phosphatase (SEAP) reporter gene on NF-κB promoter were purchased from Invivogen. The cells were cultured according to the recommendations from the company and passaged twice per week.

5.4.3 SH-SY5Y cell line

Human neuroblastoma SH-SY5Y cell line was obtained from University Medical Center of the Johannes Gutenberg University (Mainz, Germany). The original source of these two cell lines is the American Type Culture Collection (ATCC). Human neuroblastoma cell line SH-SY5Y was cultivated under standard conditions (37°C, 5% CO₂) in DMEM/F-12 (without phenol red, with 1% glutamine, Life Technologies, Darmstadt, Germany) supplemented with 10% fetal bovine serum. Cells were passaged twice a week. All experiments were performed with logarithmically growing cells.

5.5 Cytotoxicity assay

Cell viability was evaluated by resazurin assay. One hundred microliters of cell suspension with 5000 or 10000 cells per well (T98G and HEK293 cells: 5000 cells per well; SH-SY5Y cells: 10000 per well) were seeded into 96-well plates one day before the treatment with different concentrations of FAEW and fluoxetine. All these different concentrations of drugs were diluted with 200 fold medium from the stock solution. Distilled water was used as solvent control with the same dilution ratio. After 48 h, 20 µl resazurin (Sigma-Aldrich, Steinheim, Germany) 0.01% w/v in ddH₂O was added to each well and the plates were incubated at 37°C for 4 h. The fluorescence was measured with an Infinite M200 Proplate Reader (Tecan, Crailsheim, Germany) using an excitation wavelength of 544 nm and an emission wavelength of 590 nm. The toxicity of compounds was determined by means of the formula:

$$\text{Cell Viability (\% of control)} = \frac{\text{Absorption from sample well} - \text{absorption from medium}}{\text{Absorption from solvent treated cells} - \text{absorption from medium}} \times 100$$

The calculated cell viability (y-axis) was plotted against the log drug concentration (x-axis) using Microsoft Excel.

5.6 NF- κ B reporter assay

HEK293 cells stably expressing the HEK-Blue-Null vector and secreted embryonic alkaline phosphatase (SEAP) reporter gene on NF- κ B promoter were purchased from Invitrogen. The cells were cultured according to the recommendations from the company and passaged twice per week. The cells were treated with different concentrations of FAEW (60, 200, 600, 2000 μ g/ml) and fluoxetine (2, 6, 20 μ M) for 24, 48 or 72 h followed by TNF- α induction for 3 h. MG-132 was used as a positive control with treatment for only 1 h. The fluorescence was measured with an Infinite M200 Proplate Reader (Tecan, Crailsheim, Germany) with the wavelength of 630 nm. Background value caused by the medium was deducted for all the wells. The inhibition effects of FAEW and fluoxetine towards NF- κ B activity were calculated by comparison with untreated TNF- α control.

5.7 Measurement of reactive oxygen species with flow cytometry

H₂DCFH-DA (Sigma-Aldrich, Steinheim, Germany) is an indicator dye used for the highly sensitive and quantifiable detection of ROS. H₂DCFH-DA is cleaved by cytoplasmic esterases into 2', 7'-dichlorodihydrofluorescein (H₂DCF), if it diffuses into the cells. In the presence of hydrogen peroxide, H₂DCF is oxidized to the fluorescent molecule dichlorofluorescein (DCF) by peroxidases. The fluorescent signal emanating from DCF can be measured and quantified by flow cytometry [269-271]. Briefly, 2×10^5 /well T98G cells or 4×10^5 /well SH-SY5Y cells were cultured in 6-well plates, and FAEW extract and fluoxetine with different concentrations were added to the medium the day after the cells attached. Distilled water was used as solvent control.

After 24 h incubation, the medium was removed and the cells were washed three times with PBS, 10 μ M H₂DCFH-DA was incubated for 30 min in the dark at 37 °C. Subsequently, the cells were washed with PBS three times and resuspended in PBS containing hydrogen peroxide (H₂O₂, 200 μ M) (Sigma-Aldrich, Steinheim, Germany) or only PBS, respectively, for 15 min. The samples were immediately measured in a FACS Calibur flow cytometer (Becton-Dickinson, Heidelberg, Germany). For each sample, 1×10^4 cells were counted. DCF was measured at 488 nm excitation and detected using a 530/30 nm bandpass filter. All parameters were plotted on a logarithmic scale. Cryptographs were analyzed using FlowJo software (Celeza). All experiments were performed at least in triplicate.

5.8 Microarray gene expression profiling

5.8.1 RNA isolation

T98G cells were treated with 200 μ g/ml FAEW and 20 μ M fluoxetine or distilled water as solvent control for 48 h, and H₂O₂ (200 μ M) was added to induce oxidative stress for 6 h before total

RNA was isolated using InviTrap spin Universal RNA Mini kit (STRATEC Molecular, Berlin, Germany) according to the manufacturer's instruction. RNA concentrations were determined using a nanodrop spectrophotometer (Nanodrop Technologies, Thermo Fisher).

5.8.2 Probe labeling and hybridization

Microarray hybridizations were performed in duplicates for treated samples and for control samples by the Genomics and Proteomics Core Facility at the German Cancer Research Center (DKFZ, Heidelberg, Germany).

Briefly, 1 µg total RNA was used for complementary DNA (cDNA) synthesis, followed by an amplification/labeling step (in vitro transcription) to synthesize biotin-labeled cRNA according to the MessageAmp II aRNA Amplification kit (Ambion). Biotin-labeled cRNA samples for hybridization on Illumina Human HT-12 BeadChip arrays were prepared according to Illumina's recommended sample labeling procedure based on the modified Eberwine protocol [272]. The cRNA was column purified according to TotalPrep™ RNA Amplification Kit (Life Technologies) and eluted in 60-80 µL water. Hybridization was performed according to the manufacturer's instructions.

5.8.3 Scanning and data processing

Microarray scanning was done by the Genomics and Proteomics Core Facility at the German Cancer Research Center using an Illumina® BeadStation array scanner (Illumina), setting adjusted to a scaling factor of 1 and PMT settings at 430. Data was extracted for each individually, and outliers were removed, if the median absolute deviation (MAD) exceeded 2.5. Then, mean average signals and standard deviations were calculated for each probe. Data analysis was done by using the quantile normalization algorithm without background subtraction, and differentially regulated genes were defined by calculating the standard deviation differences of a given probe in a one-by-one comparison of samples or groups.

5.8.4 Data analysis

5.8.4.1 Chipster analysis

The expression data sets obtained were further filtered with Chipster software, which is an analysis platform for high-throughput data. It includes the steps that filtering of genes by two times standard deviation and a subsequent assessment of significance using empirical Bayes t-test ($p < 0.05$) with Bonferroni correction.

5.8.4.2 Ingenuity pathway analysis

Filtered genes were fed into Ingenuity Pathway Analysis software (IPA; Ingenuity Systems Inc.), which allows to integrate the experimental data to known biological and chemical interactions,

mechanisms and functions. It relies on the Ingenuity Knowledge Base, a frequently updated giant database of biological interactions and functional annotations gathered from literatures. Only molecules with an expression fold changes $\geq \pm 1.65$ were used for IPA analysis. Core Analyses using the Core Analysis tool were performed for all datasets to determine cellular networks and functions associated with deregulated mRNA that affected by each drug treatment. The results of the core analyses were further studied using the comparison analysis tool, offering the possibility to compare datasets of samples treated by different compounds.

5.8.4.3 Real-time reverse transcription-PCR

Real-time RT-PCR was performed with the same samples used for microarray experiments. Total RNA samples were converted to cDNA with random hexamer primers by RevertAid H Minus First Strand cDNA Synthesis Kit (Thermo Scientific, Darmstadt, Germany). Oligonucleotides were synthesized by Eurofins MWG Operon (Ebersberg, Germany). The efficiency of all primer pairs used for real-time PCR expression was better than 90%. Quantification of cDNA was performed on CFX384 Real-Time PCR Detection System (Bio-Rad, München, Germany) using a Hot Start Taq EvaGreen qPCR Mix (Axon scientific, Göttingen, Germany). RT-PCR was performed with an initial denaturation at 95°C for 10 min followed by 40 cycles including strand separation at 95°C for 15 s, annealing at 57.5°C for 40 s and extension at 72°C for 1 min. After PCR product amplification, melting curves were computed. The expression levels were normalized to the transcription level of the housekeeping gene, *RPS13*. All samples were run in duplicates and the experiment was repeated once.

Table 15. Primers for the investigated genes

Genes	Forward Primer	Reverse Primer
GCLM	CTAGACAAAACACAGTTGGAACA	ATGCAGTCAAATCTGGTGGCAT
HMOX1	GCCAGCAACAAAGTGCAAGATTC	CACCAGAAAGCTGAGTGTAAGGAC
NFE2L2	GAGAGCCCAGTCTTCATTGC	TGCTCAATGTCCTGTTGCAT

ATF4	TGACCTGGAAACCATGCCAG	AATGATCTGGAGTGGAGGAC
TXNRD1	ACCCAATTAGGAGCTCTCAGC	GGCTAACTGCCAGAGTCAGAA
HERPUD1	CTAGATGGCGAGCAGACC	GAGTCAGGTGATCCAGTCC
RPS13	GGTTGAAGTTGACATCTGACGA	CTTGTGCAACACATGTGAAT

5.9 Analysis of protein expression by Western blotting

5.9.1 Sample preparation

For adherent cells, some amount of cells (16×10^4 , 32×10^4 , and 64×10^4 for 72h, 48h and 24h, respectively) were sowed into the wells of a small flask (Thermo Scientific) one day before treatment. The cells were washed twice with PBS after treated with the indicated concentrations of the compound of interest for 24 h, 48h and 72h. Lysis buffer (M-PER Mammalian Protein Extraction Reagent, Thermo Scientific, plus protease inhibitor, Roche) containing phosphatase inhibitor (Roche) was used to extract the total protein. After shaking 30 min at 4 °C, the lysate was centrifuged at $14,000 \times g$ for 15 min. The nuclear protein extracts were prepared according to the NE-PER nuclear and cytoplasmic extraction reagent (Thermo Scientific, USA) supplemented with EDTA-free Halt Protease Inhibitor Cocktail (Thermo Scientific) according to the kit protocol. The supernatant was quantified by NanoDrop 1000 spectrophotometer. 45 μ g protein were mixed with 4 μ L 6 \times sample loading buffer and H₂O to a final volume of 24 μ L and denatured at 95°C for 10 min. All the proteins were stored for use in freezers.

5.9.2 SDS-PAGE and blotting

20 μ L protein extracts were separated on SDS-PAGE (The gel concentrations depend on the protein molecular weight, 12% for Histone, the other proteins used 10% gels) and electro blotted onto a PVDF membrane using the Mini-PROTEAN® Tetra Cell system (Bio-Rad). 3 μ L of Magic Mark Western Blot Standard protein ladder (Life Technologies) was loaded asides and run in parallel to estimate molecular weights of the protein. Samples were run through the stacking gel under 55 V and the voltage was increased up to 100 V and maintained till the end of electrophoresis. Then the separating samples were transferred to a Roti® PVDF blot membrane (Roth) by wet sandwich method at a 250 mA current for 2 h.

5.9.3 Antibody incubation and detection

After blotting, the membrane was first rinsed with TBST and then blocked with 5% (w/v) bovine serum albumin in TBST for 1 h at room temperature. The blocked membrane was subsequently incubated overnight at 4 °C with specific primary antibodies (Cell Signaling) that diluted 1 : 2000 in blocking solution. After washing for three times with TBST for 10 min, the membrane was incubated for 1 h at room temperature with HRP-conjugated secondary antibody (Cell Signaling) (1 : 3000 in blocking solution). After the membrane was washed with TBST (3 \times 10 min), the immunoreactivity was revealed by use of a Luminata Classico Western HRP Substrate (Millipore Corporation), and the densities of the protein bands were quantified by FluorChem Q software (Biozym Scientific Company). β -actin served as the internal control for total and

cytoplasmic protein. Histone, TATA-binding protein (TBP) and Lamin A/C levels served as the internal control for nuclear protein.

5.10 Chromatography analysis

5.10.1 Isolation of compounds from FAEW

The FAEW extract (2 g) was dissolved in DMSO and bound to 2 g of C18 material (Merck Lichroprep RP-18, 25-40 μm), which was then dried by lyophilization. Solid phase extraction (Agilent MegaBE-C18, 10 g) was performed by using a step gradient. The first fraction was eluted with 100% H_2O and discarded. Intermediate I (227.5 mg) was eluted with 15% MeCN and intermediate II (81.9 mg) with 30% MeCN. Preparative HPLC with intermediate I (MeCN/ H_2O with 0.1% TFA gradient, 5% MeCN to 25% MeCN in 40 min, 21.2 ml/min, Agilent Eclipse XDB-Phenyl, 5 μm , 21.2 \times 150 mm) yielded FAEW-1 (3.2 mg, RT 18-18.5 min), FAEW-2 (18.3 mg, RT 18.75-19.5 min), FAEW-3 (6.4 mg, RT 27.75 min), and FAEW-4 (1.1 mg, RT 36 min). FAEW-5 (2.3 mg, RT 15.5 min), FAEW-6 (1.9 mg, RT 20.6 min), FAEW-7 (2.1 mg, RT 22.3 mg), FAEW-8 (1.3 mg, RT 27.3 min), and FAEW-9 (1.0 mg, RT 31.8 min) were isolated by semi-preparative HPLC with intermediate II (MeCN / H_2O with 0.1% TFA gradient, 17% MeCN to 33.2 % MeCN in 38 min, 4 ml/min, Agilent Eclipse XDB-Phenyl, 5 μm , 9.4 \times 250 mm).

5.10.2 Structure identification

NMR and MS methods were used to identify the structures of the isolated compounds, the method and results were attached as **supplementary information**.

5.11 Molecular Docking

Ten compounds identified in the FAEW extract (albiflorin, paeoniflorin, baicalin, 1- (2, 4-dihydroxyphenyl) - 3 - hydroxyl - 3 - (4 - hydroxyphenyl) - 1 - propanone (β - hydroxyl - DHP), ononin, isoliquiritin, isoliquiritin apioside, liquiritin, oroxyloside, pentagalloyl- β -D-glucose) were selected for the *in silico* molecular docking analyses together with the anti-depressant drug fluoxetine and the known KEAP1 inhibitor, *N, N'*- naphthalene - 1, 4 - diylbis (4 - methoxybenzenesulfonamide) (PubChem ID: IQK) [115] in order to compare their binding affinity and docking poses on KEAP1. The known inhibitor for I κ K, MG-132 (PubChem ID: 462382) was selected as a standard to compare its binding modes with other compounds [273]. The PDB structure file of the protein was downloaded from RCSB Protein Data Bank (<http://www.rcsb.org/pdb/home/home.do>). All bound water molecules and ligands were eliminated from the protein and polar hydrogen was added. 3D structures of these compounds were downloaded from PubChem, ChemSpider was used to convert mol files to pdb file after checking absolute and relative configuration. Molecular docking was then carried out with

AutoDock 4.2 (The Scripps Research Institute, La Jolla, CA) following a protocol previously reported by us[274]. Docking parameters were set to 250 runs and 25,000,000 energy evaluations for each cycle. VMD (Visual Molecular Dynamics) was used for visualization of the binding modes obtained from docking. The average of the lowest binding energy of three runs was taken into account.

5.12 Literature search

The PubMed database was searched with the corresponding compound name as the key word. Identified literature was classified into *in vitro*, *in vivo* or clinical studies to give a retrospective summary of the current state of knowledge. To search the published studies of the compounds from FAEW on NF- κ B or ROS, NF- κ B and the corresponding compound name were used as the key words.

7.1 Isolation

Standardized HPLC/MS method:

Column: Agilent XDB Phenyl, 3.5 μm , 150 x 3 mm
Temperature: 40 °C (column oven)
Solvents: H₂O with 0.1% HCOOH and MeCN
Gradient: 1% MeCN to 50 % MeCN in 40 min
50% MeCN to 100 % MeCN in 5min
100% MeCN isocratic for 2 min
100% MeCN to 1 % MeCN in 1 min
Flow: 0.45 ml/min
MS: Ion source: APCI
Capillary voltage: 3500 V (pos.)/2200 V (neg.)
Corona current: 4.0 μA (pos.)/12 μA (neg.)
Drying Gas Flow: 6.0 l/min
Nebulizer pressure: 50 psig
Drying Gas Temperature: 350 °C
Vaporizer Temperature: 400 °C

Crude extract “free and easy wanderer“(HPLC-MS chromatogram, 250 nm)

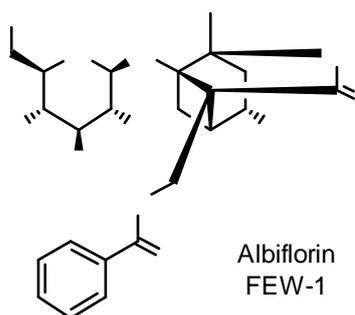

HPLC chromatogram (250 nm) of the crude extract (*Free and Easy Wanderer*), isolated compounds are marked

7.2 Structure identification

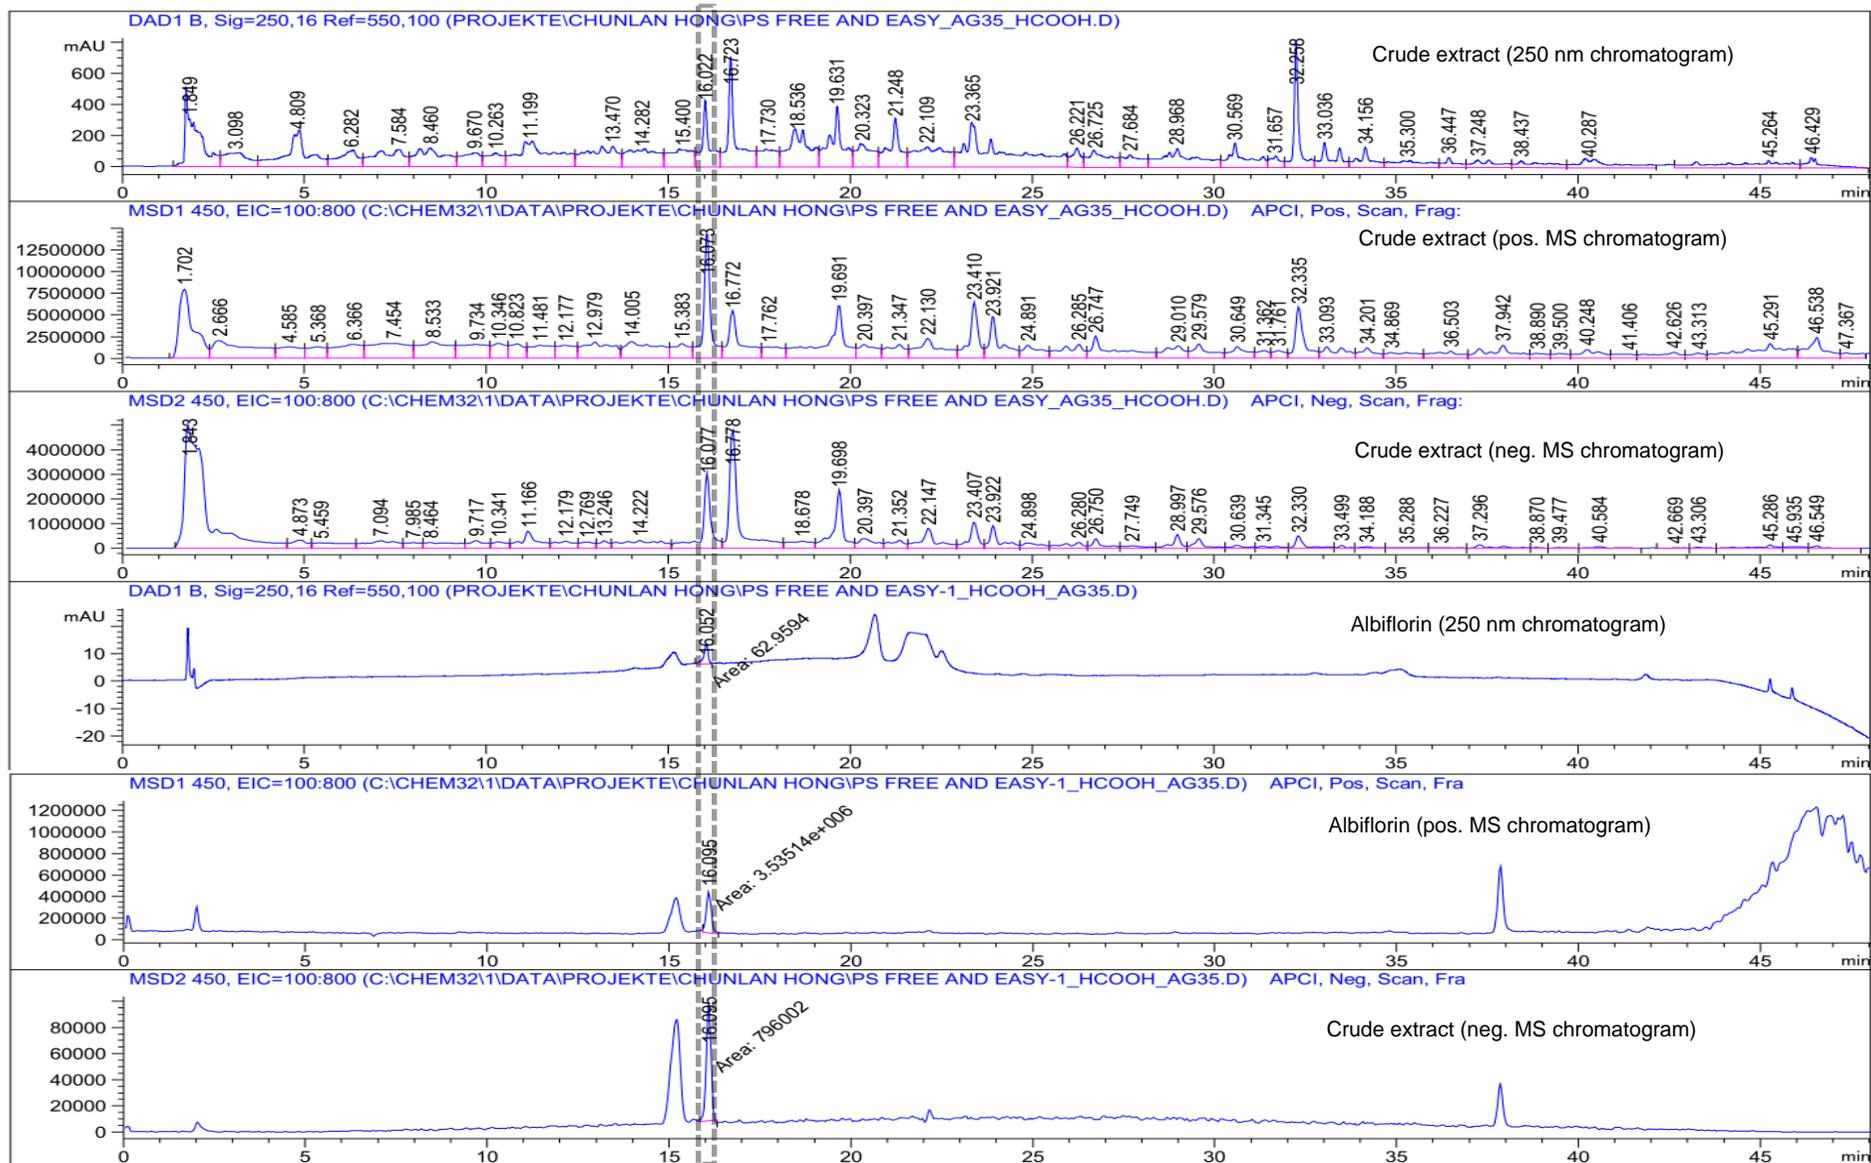

7.2.1 FAEW-1 Albiflorin

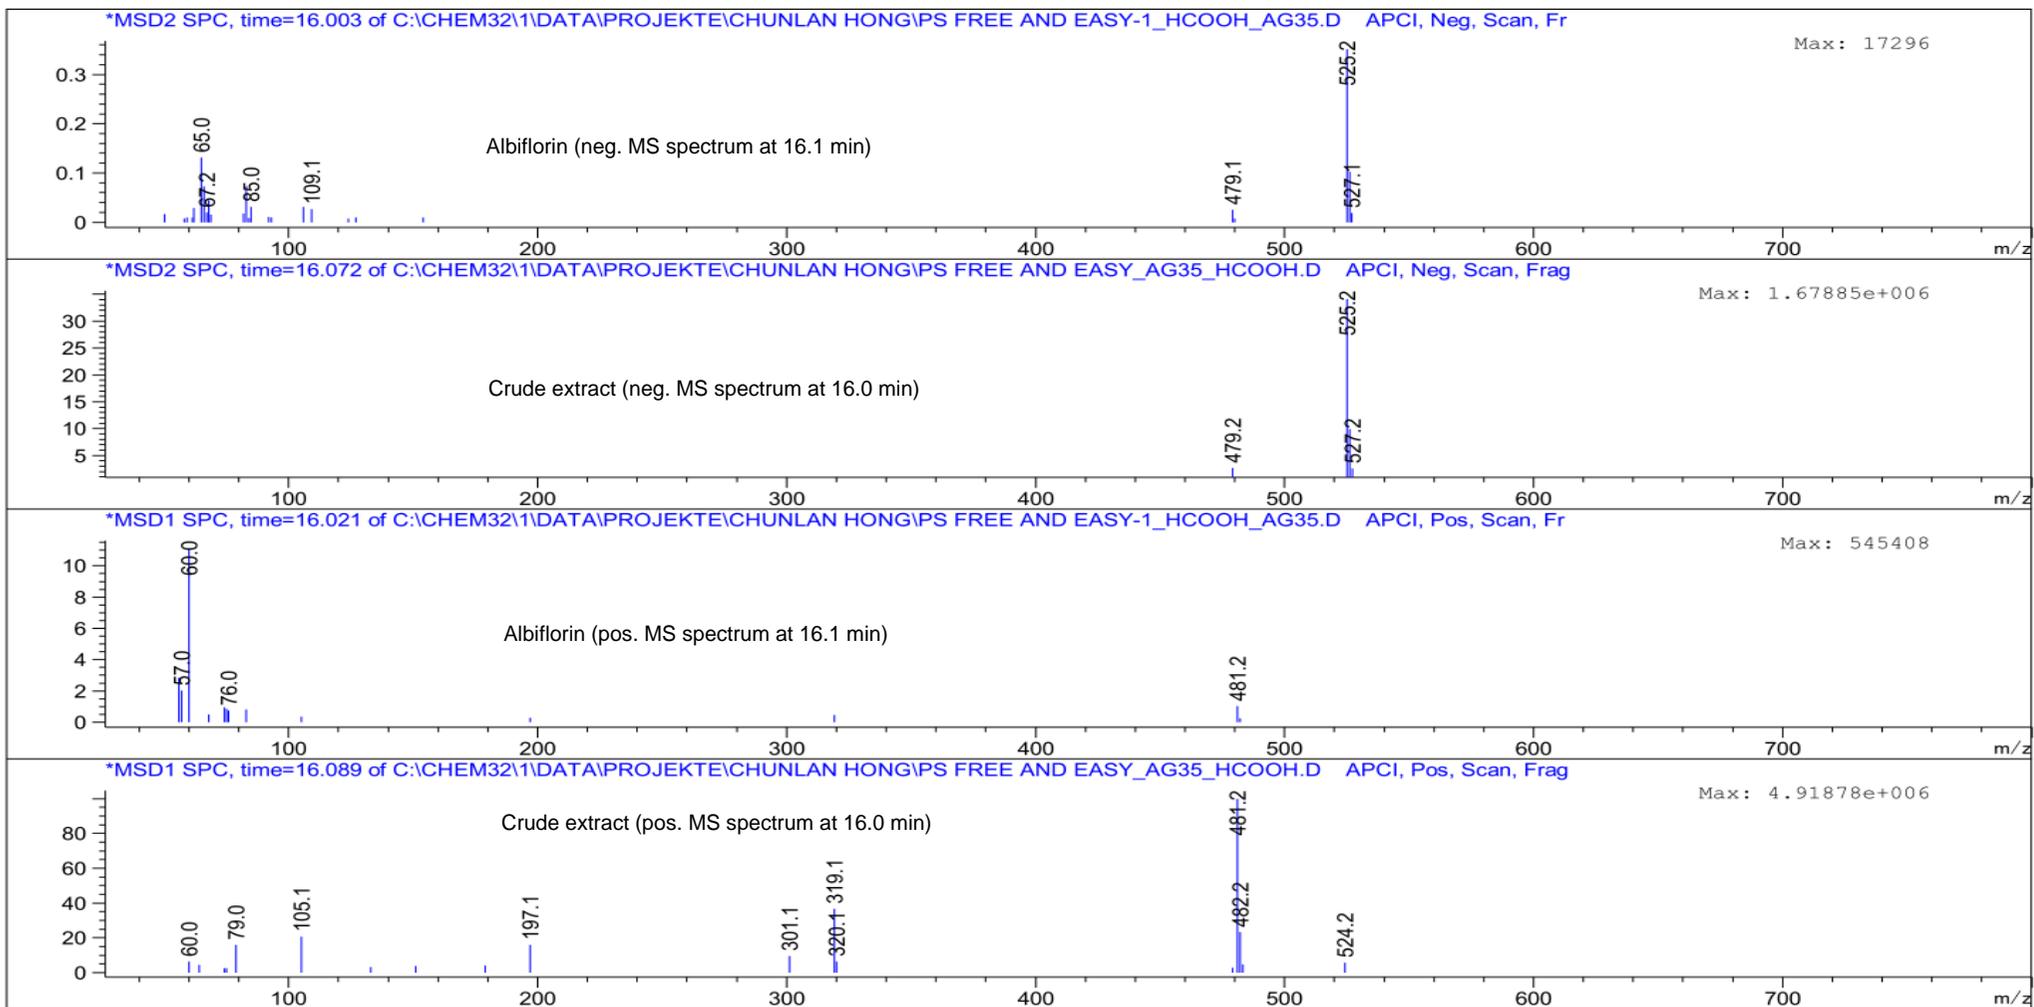

Brown oil, $[\alpha]_{D29} = -7.3$ ($c = 0.07$, MeOH), ESI-MS $m/z = 481.2$ $[M+H]^+$, HR-ESI-MS $m/z = 503.1529$ calculated for $[C_{23}H_{28}O_{11}+Na]^+$; found: 503.1546.

1H NMR, COSY (600 MHz, Methanol- d_4) δ 8.11 – 8.07 (m, 2H, H-2''/H-6''), 7.64 – 7.60 (m, 1H, H-4''), 7.52 – 7.48 (m, 2H, H-3''/H-5''), 4.80 (d, $J = 12.2$ Hz, 1H, H-8), 4.68 (d, $J = 12.2$ Hz, 1H, H-8), 4.53 (d, $J = 7.6$ Hz, 1H, H-1'), 4.27 (dd, $J = 6.6, 4.9$ Hz, 1H, H-4), 3.85 (dd, $J = 11.8, 1.5$ Hz, 1H, H-6'), 3.61 – 3.58 (m, 1H, H-6'), 3.27 – 3.24 (m, 1H, H-3'), 3.24 – 3.19 (m, 3H, H-2', H-4', H-5'), 2.92 (dd, $J = 7.8, 4.9$ Hz, 1H, H-5), 2.80 (dd, $J = 11.0, 7.8$ Hz, 1H, H-7), 2.41 (dd, $J = 15.4, 6.6$ Hz, 1H, H-3), 2.05 (d, $J = 11.0$ Hz, 1H, H-7), 2.00 (dd, $J = 15.4, 1.5$ Hz, 1H, H-3), 1.52 (s, 3H, C-2-Me).

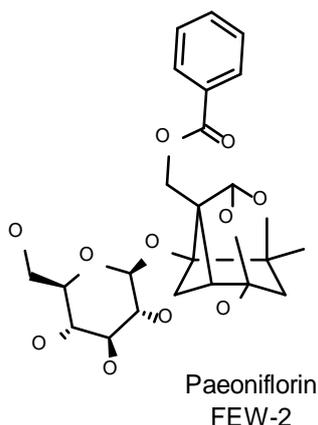

^{13}C NMR, HSQC, HMBC (151 MHz, MeOD) δ 178.0 (C-9), 167.9 (C-1''-CO), 134.4 (C-4''), 131.2 (C-1''), 130.8 (C-2''/C-6''), 129.7 (C-3''/C-5''), 100.1 (C-1'), 93.5 (C-2), 86.9 (C-1), 78.2 (C-5'), 78.0 (C-3'), 74.8 (C-2'), 71.6 (C-4'), 68.4 (C-4), 62.8 (C-6'), 62.0 (C-8), 56.9 (C-6), 41.7 (C-5), 41.6 (C-3), 28.5 (C-7), 20.6 (C-2-Me).

8 Appendix

8.1 Publications

Original publications as first author

- **Hong C**, Cao J, Wu CF, Kadioglu O, Schüffler A, Kahl U, Klauck SM, Opatz T, Thines E, Paul NW, Efferth T. The Chinese herbal formula *Free and Easy Wanderer* ameliorates oxidative stress through KEAP1-NRF2/HO-1 pathway. *Sci Rep.* 2017, 7(1):11551.
- **Hong C**, Schüffler A, Kahl U, Cao J, Wu CF, Opatz T, Thines E, Efferth T. Identification of NF- κ B as Determinant of Posttraumatic Stress Disorder and Its Inhibition by the Chinese Herbal Remedy *Free and Easy Wanderer*. *Front Pharmacol.* 2017, 8: 181.
- **Hong C**, Efferth T. Systematic Review on Post-Traumatic Stress Disorder among Survivors of the Wenchuan Earthquake. *Trauma Violence Abuse.* 2016, 17(5): 542-561.

Original publications as co-author

- Efferth T, Banerjee M, Paul NW, Abdelfatah S, Arend J, Elhassan G, Hamdoun S, Hamm R, **Hong C**, Kadioglu O, Naß J, et al. Biopiracy of natural products and good bioprospecting practice. *Phytomedicine.* 2016, 23(2): 166-73
- Wu CF, **Hong C**, Klauck SM, Lin YL, Efferth T. Molecular mechanisms of rosmarinic acid from *Salvia miltiorrhiza* in acute lymphoblastic leukemia cells. *J Ethnopharmacol.* 2015, 176: 55-68.

Conference paper

- **Hong C**, Cao J, Efferth T. Posttraumatic stress disorder among earthquake survivors of the Wenchuan area (Sichuan, China). *Eur J Psychotraumatol.* 2014, 5: 26531.

Poster

➤ Sep 2-5, 2017, Paris: 30th ECNP Congress of Applied and Translational Neuroscience
Poster presentation: The application of TCM to the treatment of psychiatric disorders: *in vitro* antioxidative and anti-inflammatory effect of *free and easy wanderer*

- Jul 24-28, 2017, Mainz: International Conference on Science and Society: Biopiracy and Phytomedicine

Oral presentation: The Chinese herbal formula *Free and Easy Wanderer* ameliorates oxidative stress through KEAP1-NRF2/HO-1 pathway

- Mar 14, 2016, Mainz: “Mensch und Medizin: Kosten - Nutzen - Gesundheit?” held by Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) “Life Science - Life Writing” Research Training School

Poster presentation: Life Science and Humanities: Therapeutic Approach of Posttraumatic Stress Disorder by Traditional Chinese Medicine

- Sep 27-29, 2015, Barcelona: 12th World congress of Chinese medicine

Oral presentation: Temporality, Materiality and Traditional Chinese medicine

- Dec 2-4, 2015, Prague: 15th International Forum on Mood and Anxiety Disorders

Poster presentation: A meta-analysis on microarray-based transcriptome-wide mRNA expression profiling of patients with posttraumatic stress syndrome suggesting an important role of NFκB

- Oct 17-19, 2014, Hangzhou: “Post-Traumatic Stress: State of the Art Research and Clinical Implications for China” held by the International Society for Traumatic Stress Studies

Oral presentation: Posttraumatic stress disorder (PTSD) among earthquake survivors of the Wenchuan area (Sichuan, China)

8.2 Curriculum Vitae
