2. Gutachterin:

Tag des öffentlichen Promotionskolloquiums: 19.08.2021

D77 (Dissertation Universität Mainz)

Urheberschaftserklärung

Ich, Erika Diehl (née Pfeifer), versichere, dass ich die vorliegende Dissertation mit dem Titel „Elucidating the protein interactome of the human ion channel TRPV4“ selbst verfasst, nicht andere als die in ihr angegebenen Quellen oder Hilfsmittel benutzt, alle vollständig oder sinngemäß übernommenen Zitate als solche gekennzeichnet sowie die Dissertation in der vorliegenden oder einer ähnlichen Form noch bei keiner anderen in- oder ausländischen Hochschule anlässlich eines Promotionsgesuchs oder zu anderen Prüfungszwecken eingereicht habe.

Für meine Eltern, Familie und Freunde. Danke für Alles.

"Nature always wins but that doesn't mean we have to bow or grovel to it. That maybe even if we're not always glad to be here, it's our task to immerse ourselves anyway: wade straight through it, right through the cesspool, while keeping eyes and hearts open."

- The Goldfinch, Donna Tartt

Summary

Transient receptor potential vanilloid 4 (TRPV4) is an integral membrane protein which functions as a non-selective cation channel. TRPV4 plays a central role in mammalian sensory perceptions like the sense of touch and temperature sensing. Although research steadily increases, our knowledge of TRPV4 as well as other TRP superfamily members and their complex regulation mechanisms still remain poorly understood. TRPV4 is also involved in not well-characterized diseases, including peripheral neuropathies and skeletal dysplasias caused by channel point mutations. Many of these point mutations are located in the human TRPV4 N-terminus (hsV4N). The either solely skeletal or neuronal impact of these mutations led to the assumption that hsV4N may interact with tissue specific proteins and that these protein-protein interactions would then be specifically disturbed in the presence of disease-causing point mutations. To this point, data on the protein interactome of hsV4N are fragmentary and further investigations to shed light on the complex interaction network of TRPV4 are required.

In this work, recombinant hsV4N as well as the TRPV4 ankyrin repeat domain (hsV4 ARD), as a part of hsV4N and notorious hot-spot for disease causing mutations, were investigated with regard to their protein interactome in HEK293 cells using ultra high-definition mass spectrometry (UDMS^E) in cooperation with the RG [REDACTED] (University Medicine Mainz, JGU Mainz). The interactome results revealed ribonucleotide binding proteins as a new potential class of TRPV4 interacting proteins and indicate hsV4N as an until now unknown hub in the regulatory mechanism of cytoplasmic ribonucleoprotein granule formation. These findings were underlined by the here shown direct interaction *in vitro* between recombinant hsV4 ARD and the granule nucleating protein DDX3X. Interestingly, this interaction increased in the presence of the neuropathy-causing R232C mutation in hsV4 ARD.

Another hsV4 ARD interacting protein studied in the course of this thesis is the small GTPase RhoA. It was shown via nuclear magnetic resonance spectroscopy (NMR) that recombinantly expressed ¹⁵N-RhoA directly interacts with hsV4 ARD and that this interaction significantly decreases in the presence of the neuropathy-causing mutation R269C in hsV4 ARD (hsV4

ARD R269C). In a cooperation with the RG [REDACTED] (Department of Neurology, Johns Hopkins University School of Medicine) it was shown that this neuropathy mutation-dependent loss-of-interaction leads to aberrant neurite-growth *in cellulo* and *Drosophila melanogaster*. These findings strongly hint at that the disruption of TRPV4-RhoA interaction is one determinant of the tissue-specific toxicity of TRPV4 neuropathy mutations.

An additional determinant for the tissue-specific toxicity of TRPV4 neuropathy mutations could be the loss-of-interaction between neuropathy-causing TRPV4 R269C and the neurospecific protein and known direct TRPV4-binding partner PACSIN1 that was demonstrated in this work. PACSIN1 dampens hypotonicity-induced TRPV4-dependent Ca²⁺-influx in transiently transfected HEK293 cells. This ability to desensitize TRPV4 to hypotonicity is lost in the presence of the neuropathy-causing mutation TRPV4 R269C, probably due to a loss-of-interaction as shown via co-immunoprecipitation. Strikingly, the PACSIN1-orthologue PACSIN3 retained its TRPV4 interaction and modulation upon hypotonicity. Further comprehensive studies with PACSIN chimeras hint towards different binding mechanisms between TRPV4 and PACSIN1 or TRPV4 and PACSIN3, respectively.

Furthermore, in this thesis the foundation was laid to elucidate the possible role of post-translational modifications in TRPV4s protein-protein interactions. It was shown that hsV4N directly interacts with the E3 ubiquitin ligase ITCH and that lysine residues in close proximity to important regulatory sites within the intrinsically disordered region (IDR), preceding the hsV4 ARD in hsV4N, are ubiquitinated.

Thus this thesis provides a comprehensive study of new potential TRPV4 protein interactors and first explanations for the tissue-specificity of neuropathy-causing TRPV4 mutations.

Zusammenfassung

Transient receptor potential vanilloid 4 (TRPV4) ist ein integrales Membranprotein, das als nicht-selektiver Kationenkanal fungiert. TRPV4 spielt eine zentrale Rolle bei Sinneswahrnehmungen von Säugetieren wie dem Tastsinn und der Temperaturwahrnehmung. Obwohl die Forschung über TRP-Kanäle stetig zunimmt, ist unser Wissen über TRPV4 sowie über andere Mitglieder der TRP-Superfamilie und deren komplexe Regulationsmechanismen noch immer wenig verstanden. TRPV4 ist auch an nicht gut charakterisierten Krankheiten beteiligt, darunter periphere Neuropathien und skeletale Dysplasien, die durch Punktmutationen im Kanal verursacht werden. Viele dieser Punktmutationen befinden sich im N-Terminus von humanem TRPV4 (hsV4N). Die entweder ausschließlich skeletale oder neuronale Auswirkung dieser Mutationen führte zu der Annahme, dass hsV4N mit gewebespezifischen Proteinen interagieren könnte und dass diese Protein-Protein-Interaktionen bei Vorhandensein von krankheitsverursachenden Punktmutationen dann spezifisch gestört sein würden. Bis zu diesem Zeitpunkt sind die Daten über das Proteininteraktom von hsV4N lückenhaft und weitere Untersuchungen, die mehr Klarheit über das komplexe Interaktionsnetzwerk von TRPV4 bringen sollen, sind erforderlich.

In dieser Arbeit wurden rekombinantes hsV4N sowie die TRPV4-Ankyrin-Repeat-Domäne (hsV4-ARD), als Teil von hsV4N und notorischer *hot spot* für krankheitsverursachende Mutationen, hinsichtlich ihres Proteininteraktoms in HEK293-Zellen mittels Ultra-High-Definition-Massenspektrometrie (UDMS^E) in Kooperation mit der RG [REDACTED] (Universitätsmedizin Mainz, JGU Mainz) untersucht. Die Interaktom-Ergebnisse enthüllten Ribonukleotid bindende Proteine als eine neue potentielle Klasse von TRPV4-interagierenden Proteinen und weisen darauf hin, dass hsV4N ein bisher unbekannter Knotenpunkt im Regulationsmechanismus von der Bildung von zytoplasmatischen Ribonukleoproteingranula sein könnte. Diese Erkenntnisse wurden durch die hier gezeigte direkte Interaktion *in vitro* zwischen rekombinantem hsV4 ARD und dem Granula nukleierenden Protein DDX3X untermauert. Interessanterweise verstärkte sich die Protein-Protein-Interaktion von DDX3X mit hsV4 ARD in Gegenwart der neuropathieverursachenden R232C-Mutation in hsV4 ARD.

Ein weiteres hsV4 ARD interagierendes Protein, das im Rahmen dieser Arbeit untersucht wurde, ist die kleine GTPase RhoA. Mittels Kernspinresonanzspektroskopie (NMR) wurde gezeigt, dass rekombinant exprimiertes ¹⁵N-RhoA direkt mit hsV4 ARD interagiert und dass diese Interaktion in Gegenwart der Neuropathie verursachenden Mutation R269C in hsV4 ARD (hsV4 ARD R269C) signifikant abnimmt. In einer Kooperation mit der RG [REDACTED] (Department of Neurology, Johns Hopkins University School of Medicine) konnte gezeigt werden, dass dieser mutationsabhängige Interaktionsverlust zu aberrantem Neuriten-Wachstum *in cellulo* und *Drosophila melanogaster* führt. Diese Befunde weisen stark darauf hin, dass die Störung der TRPV4-RhoA-Interaktion eine Determinante für die gewebespezifische Toxizität von TRPV4-Neuropathie-Mutationen ist.

Eine weitere wichtiger Faktor für die gewebespezifische Toxizität von TRPV4-Neuropathiemutationen könnte der hier gezeigte Verlust der Interaktion zwischen der Neuropathie verursachenden TRPV4 R269C und dem neurospezifischen Protein und bekannten direkten TRPV4-Bindungspartner PACSIN1 sein. PACSIN1 schwächt den Hypotonie induzierten TRPV4-abhängigen Ca²⁺-Influx in transient transfizierten HEK293-Zellen ab. Diese Fähigkeit, TRPV4 gegenüber Hypotonie zu desensibilisieren, geht in Gegenwart der Neuropathie verursachenden Mutation TRPV4 R269C verloren. Dies geschieht wahrscheinlich aufgrund eines Interaktionsverlustes, wie durch Co-Immunopräzipitation gezeigt werden konnte. Auffallend ist, dass das PACSIN1-Ortholog PACSIN3 seine TRPV4-Interaktion und -Modulation bei Hypotonie beibehält. Weitere umfangreiche Untersuchungen mit PACSIN-Chimären deuten auf unterschiedliche Bindungsmechanismen zwischen TRPV4 und PACSIN1 bzw. TRPV4 und PACSIN3 hin.

Weiterhin wurde in dieser Arbeit der Grundstein gelegt, um die mögliche Rolle von posttranslationalen Modifikationen in den Protein-Protein-Interaktionen von TRPV4 aufzuklären. Es konnte gezeigt werden, dass hsV4N direkt mit der E3-Ubiquitin-Ligase ITCH interagiert und dass Lysinreste in unmittelbarer Nähe zu wichtigen regulatorischen Stellen innerhalb der intrinsisch ungeordneten Region (IDR), die der hsV4-ARD in hsV4N vorgelagert ist, ubiquitiniert sind.

Somit liefert diese Arbeit eine umfassende Studie neuer potentieller TRPV4-Proteininteraktoren und erste Erklärungen für die Gewebespezifität der Neuropathie verursachenden TRPV4-Mutationen.

1 Introduction

1.1 A little grasp of the TRP channel world

TRP stands for *Transient Receptor Potential* - a term introduced by Cosens *et al.* in a publication with the title "Abnormal Electroretinogram from a *Drosophila* Mutant".¹ In this paper, Cosens *et al.* described transient instead of steady electric activities in *Drosophila melanogaster* retinas upon light stimuli, caused by a spontaneous mutation in these flies. It took another 20 years to identify and characterize the responsible *Drosophila melanogaster* *trp* gene locus and to show that this gene encodes for an integral membrane protein. In 1992 Baruch Minke and Roger Hardie showed this integral membrane protein to be a Ca^{2+} -gating ion channel.⁵ The identification of mammalian TRP channels not just only founded a whole new protein superfamily, consisting of 28 members divided into 6 subfamilies (figure 1.1) - intensive

Figure 1.1: **Multiple alignment phylogenetic tree of the mammalian TRP channel superfamily.** The phylogenetic tree shows the relations between the TRP subfamilies based on sequence similarity. TRPP (polycystin), TRPC (canonical), TRPM (melastatin), TRPA (ankyrin), TRPV (vanilloid) and TRPML (mucolipin). Note that TRPC2 is a pseudogene in humans and therefore was substituted with the mouse variant. Multiple sequence alignment and phylogenetic tree generation was performed with ClustalW2 at the EMBL-EBI server.² Tree Rendering was performed with DrawTree 3.66 via <http://www.phylogeny.fr/>.^{3,4}

investigations also underpinned again a common catch in biochemical nomenclature: the initial name often underestimates the plethora of physiological functions the proteins are covering - and the TRP superfamily is a remarkable example for this.⁶

TRP channels are expressed at the plasma membrane and/or in intracellular organelle membranes of almost every cell and tissue type. With their function as tetrameric cation channels and slight preference for Ca^{2+} , TRP channels play an important role in different physiological processes including muscle contraction, cell proliferation or neurotransmitter release.⁶ In addition, since they couple intra- and extracellular signals to flux ions across the membrane, TRP channels are also important mediators between the two membrane sides and are therefore well suited to fulfill their role in somato-, osmo-, thermo- and photosensation as well as nociception, amongst others sensory perceptions.⁷⁻¹³ *In cellulo* experiments revealed a broad diversity among TRP channel activating/modulating stimuli, including ligand activation by exogenous synthetic and natural chemical compounds or endogenous lipids and purine nucleotides as well as temperature and cell swelling. This polymodality hints towards to a highly complex and diverse regulation of TRP channels, defining their (patho)physiological role by the respective cellular context in terms of the lipid- and proteome, for example. As diverse as the activation stimuli and physiological roles are the pathological outcomes of mutated TRP channels - diseases which can be grouped into so called channelopathies.¹⁴⁻¹⁷ TRP channelopathies span from kidney disorders (e.g. focal segmental glomerulosclerosis, TRPC6 OMIM:603965, polycystic kidney disease, TRPP2 OMIM:613095), skeletal dysplasias (e.g. metatropic dysplasia, TRPV4 OMIM:156530), lysosomal storage disorders (e.g. mucopolysaccharidosis type 4, TRPML1 OMIM:252650), skin disorders (e.g. erythrokeratodermia variabilis et progressiva 6, TRPM4 OMIM: 618531) to neurodegenerative disorders (e.g. hereditary motor and sensory neuropathy type IIC, TRPV4 OMIM:606071).

TRP channels share structural motifs among each other, but also exhibit structural diversity - especially between the different TRP subfamilies. Each TRP monomer consists of structurally conserved six transmembrane helices (S1-6) with a so-called reentrant loop between S5 and 6, forming the ion pore in a TRP tetramer (figure 1.2 A). S1-4 form the so-called voltage sensor-like domain (VSLD), which affects channel gating by ligand binding.¹⁸⁻²⁰ The biggest structural differences between TRP channels are displayed within the intracellular N- and C-termini as well as by large extracellular domains present in some subfamilies. Due to these differences, the mammalian TRP superfamily can be divided into two groups. Group 1 (TRPM, TRPA, TRPV and TRPC, figure 1.2 B) includes the TRP subfamilies with large cytosolic N-termini,

Figure 1.2: **One representative structure of each human TRP subfamily.** **A** Each TRP monomer consists of a structurally conserved core of six transmembrane helices (S1-6) shown here as ribbon diagram (left) and topology model (right). **B** Selected members belonging to group 1 of human TRP subfamilies, including TRPV6, TRPA1, TRPC3 and TRPM2. Monomers are highlighted in violet. For TRPV6, TRPA1 and TRPC3, only the ankyrin repeat domains (which are mostly α -helical structures) of the whole cytosolic N-terminus of respective TRP channel are resolved. The preceding parts are putatively unstructured and therefore not resolved in shown structures. For TRPM2 and the other TRPM channels a large so-called melastatin homology region defines the N-terminus.²¹⁻²⁴ **C** Selected members belonging to group 2 of human TRP subfamilies, including TRPML1 and TRPP2 with their extracellular/luminal domains spanning from the S1 to S2 transmembrane helix.

harboring pivotal regulatory sites like lipid binding sites or regulatory domains like ankyrin repeat domains (ARDs). ARDs are α -helical motifs which serve as protein interaction platforms and play a role in ion channel assembly.²⁵⁻²⁸ Group 2 TRP channels (TRPP and TRPML, figure 1.2 C) are characteristic for their large domains spanning from S1 to S2, either being called extracellular domain or extraluminal domain in the case of lysosomal localization of TRPML. While structural investigations of (human) TRP channels immensely advanced in the past 10 years, the elucidation of human TRP channel protein interactomes is still underrepresented.²⁰ Figure 1.3 shows current protein-protein interaction (PPI) networks deposited in the manually curated TRP channel PPI database TRIP.^{29,30} Strikingly, most of the shown PPIs were determined with rodent proteins, whereas only a minority depicts PPIs with human proteins (see also table 6.1). Besides the prominent Ca^{2+} -binding protein Calmodulin and other calcium sensors like ALG-2 and NCS-1, especially cytoskeletal associated (KIF3A, α -actinins, Tropomyosin 1) and scaffolding proteins (AKAP5, NHERF-1, Homer-1) are represented. Furthermore, interactors like Orai1, IP3R3 and RyR underline the role of TRP channels in store operated Ca^{2+} entry. Most of these proteins are part of large protein complexes to achieve physiological func-

tions and tightly regulate each other. As aberrant human TRP channels are the cause of several, also tissue and cell-specific diseases, it is pivotal to determine these protein complexes and ultimately also the regulation mechanisms between distinct PPIs to understand the pathophysiological outcomes of mutated TRP channels. Here, the N- and C-termini of TRP channel are especially interesting, as they harbor important interaction sites like ankyrin repeat domains but also are accessible for a broad range of possible protein interactors due to their cytosolic protrusion (figure 1.2 B). Almost all PPI studies with TRP channels were conducted with full-length channels. Additionally to the need for a more comprehensive knowledge of overall TRP channel PPIs, it is also pivotal to determine the exact interaction sites at the channels. This leads to a better understanding of these PPIs and ultimately provide modulation possibilities of aberrant PPIs due to mutated TRP channels in diseases.

Figure 1.3: **TRP channel PPI network extracted from the TRIP Database.** The majority of the shown PPIs are with rodent proteins (grey nodes), whereas only a minority depicts PPIs with human proteins (purple nodes). Node colors of TRP subfamilies are indicated in the figure. See figure 6.1 for labeled nodes. Network was rendered via with Cytoscape 3.8.0.

1.2 TRPV4 - the wild child amongst TRPV channels?

In their review "*The puzzle of TRPV4 channelopathies*" published in 2013, Bernd Nilius and Thomas Voets described TRPV4 as follows:

*"TRPV4 could be compared to Proteus, a God of the sea in Greek mythology, who has characteristics of flexibility, versatility, mutability and adaptability, emerges in many shapes and can appear in frightening forms."*³¹

This description is still surprisingly accurate, as in the course of this PhD thesis TRPV4 showed another similarity to the sea god. Proteus is able to prophecy the future but is almost unwilling to do so. Only to the ones who are able to capture him with cunning, Proteus will answer their questions. And just as this moody sea god, TRPV4 is unwilling to easily reveal information about its role in physiological and pathological processes. This PhD thesis shows that it took, and it is still going to take, scientific highly versatile and multi-pronged approaches to "capture" TRPV4 to get the desired information.

TRPV4 was first described as an osmoreceptor involved in systemic osmotic pressure in 2000 by Liedtke *et al.*³² Three years later, two research teams generated *trpv4* null mice and published the outcomes of this deletions in the murinal osmotic regulation.^{33,34} Liedtke and Friedmann determined systematic plasma hyperosmolality, diminished drinking and decreased vasopressin plasma levels in these mice. Vasopressin is a peptide hormone synthesized in the hypothalamus and systematically released via the posterior pituitary in response to hyperosmolality, inducing water reabsorption in the nephrons and arteriole constriction to increase the peripheral vascular resistance and arterial blood pressure. Therefore, Liedtke and Friedmann suggested that *trpv4* null mice have an impaired osmosensation in the central nervous system (CNS).³³ In contrast, Mizuno *et al.* observed a normal drinking behavior in their *trpv4* null mice and no plasma hyperosmolality. Furthermore, upon a hyperosmolal challenge due to intraperitoneal propylene glycol injection, these mice showed increased vasopressin secretion compared to wild type mice.³⁴ Taken together, these studies and later conducted *in cellulo* experiments show that TRPV4 is a pivotal key regulator in osmosensation - but how exactly TRPV4 is involved in the vasopressin-regulated osmolality homeostasis or even in the smaller cellular context of osmolarity induced cell swelling or shrinkage still remains elusive. These first descriptions of TRPV4 as a osmotically activated channel were then followed by the discoveries of other TRPV4 activation and/or modulating factors such as innocuous temperature,

chemicals like the synthetic phorbol ester 4 α -phorbol-12,13-didecanoate (4 α -PDD) or the endogenous compound 5',6'-epoxyeicosatrienoic acid (5',6'-EET) as well as plasma membrane embedded phosphoinositides like phosphatidylinositol-4,5-bisphosphate (PI(4,5)P₂).^{35–39}

Considering the relatively mild phenotypic consequences of *trpv4* null mice, resulting in fertile and viable mice with some impairments like the before mentioned altered osmosensation, impaired osteoclast differentiation as well as hearing alteration and compromised vascular endothelial functions, it is striking that mutations in TRPV4 lead to severe diseases in humans.^{31,40–45} These autosomal-dominant hereditary TRPV4 channelopathies span from relatively mild outcomes to heavily disabling or even lethal diseases which can be divided in two main groups, namely skeletal dysplasias and peripheral neuropathies.^{14,15,31,46}

Figure 1.4: **Distribution of TRPV4 channelopathy mutations.** Shown residues of channelopathy-causing TRPV4 mutations are mapped onto the cryo-EM structure of *X. tropicalis* TRPV4 (PDB:6BBJ). Skeletal dysplasia mutants are shown as green spheres, familial digital arthropathy brachydactyly (FDAB) mutations as blue spheres and peripheral neuropathy mutations as yellow spheres. Whereas skeletal dysplasia mutations are distributed over the whole channel, neuropathy-causing mutations are mainly clustered in the cytosolic ankyrin repeat domain (hsV4 ARD). Numbered mutations correspond to the human TRPV4 sequence and were investigated in the course of this thesis. The very N-terminal intrinsically disordered region (IDR, aa 1-149) is not resolved and therefore not shown in the structure. Please note that a human TRPV4 structure, also lacking the IDR, was published by Botte *et al.*, but no structure was deposited in the RSCB Protein Data Bank to date.¹⁸

To date, five skeletal dysplasias and one other skeletal disease (familial digital arthropathy brachydactyly, FDAB, OMIM: 606835) are known to be caused by TRPV4 mutations (OMIM: 605427). FDAB represents a very mild form of a TRPV4 mutation-induced bone disease, where patients appear normal at birth but develop a deforming and painful osteoarthritis due to subchondral pathology of the finger- and toe phalanges as well as the metacarpal and -tarsal bones, leading to arthropathy and brachydactyly. The FDAB-causing mutations in TRPV4 which are known to date, were discovered in three unrelated families in the third ankyrin repeat (AR3)

of TRPV4 (G270V, R271P, F273L, see also blue spheres in figure 1.4).⁴⁷ Unlike these FDAB-associated mutations, skeletal dysplasia-causing mutations are not as tightly clustered in one specific TRPV4 domain (figure 1.4). However, in sequential proximity, mutations (K276E or I331F) lead to lethal metatropic dysplasia (MD), the severe end of TRPV4 channelopathies.^{48,49} Characteristic TRPV4-associated skeletal dysplasia phenotypes are brachydactyly, short trunk and scoliosis.³¹ For lethal MD, additionally abnormally thick cartilage and congenital bone deformations were observed like hip dislocation and clubfeet, probably caused by altered endochondral ossification during the fetal development.⁴⁹ Recombinant overexpression - either in HEK293T cell lines or *Xenopus tropicalis* oocytes - of skeletal dysplasia-inducing TRPV4 mutations resulted mostly in gain-of-function channels, leading to increased Ca^{2+} -levels in these cells.⁵⁰⁻⁵² The same observations in terms of elevated basal or activated Ca^{2+} -influx activity were also made with neuropathy-causing TRPV4 mutations.^{53,54} TRPV4-associated peripheral neuropathies include two rare forms of spinal muscle arthropies (SMAs), namely congenital distal SMAs (CDSMAs, OMIM:600-175) and scapuloperoneal SMA (SPSMA, OMIM:181405). In most cases (approx. 90%), the cause of SMA is a mutation in the survival of motor neuron 1 (SMN1) protein, leading to ventral horn motor neuron degeneration and ultimately to progressive muscle wasting of voluntary muscles in the limbs and also respiratory muscles.⁵⁵ TRPV4-associated CDSMA and SPSMA primarily affect the muscles of lower limbs and for SPSMA additionally the shoulder blade muscle. While TRPV4-associated CDSMA patients do not have sensory deficits, SPSMA and the third TRPV4-associated neuropathy, Charcot-Marie-Tooth Type 2C (CMT2C, OMIM:606071), share sensory deficits and vocal cord paresis as symptoms. Furthermore, CMT2C patients show, in contrast to the congenital conditions in CDSMA and SPSMA, a progressive and non-congenital muscle weakness and atrophy of distal muscles. Strikingly, mutations causing the before mentioned peripheral neuropathies especially cluster in ankyrin repeats 2 and 4 of the TRPV4 ankyrin repeat domain, whereas skeletal dysplasia causing mutations are spread all over the full-length channel, as shown in figure 1.4.^{27,31,49,56} Amongst the TRPV subfamily, only TRPV4 exhibits such a plethora of direct disease-causing mutations. To date, only two other clinical syndromes are known to be caused by TRPV subfamily members. TRPV3 is the until now only known cause of the Olmsted syndrome (mutilating palmo-plantar keratoderma with periorificial keratotic plaques, OMIM: 614594), a very rare congenital skin disorder leading to very thick skin on the hand palms and feet soles combined with severe hyperkeratotic plaques around the mouth region. Olmsted syndrome-causing TRPV3 mutations are either located in the loop between transmembrane helices S4 and 5 (G537S and G573C) or in the C-terminus (W629G) and also result, like the disease-causing mutations in TRPV4, in

gain-of-function channels. On the other hand, most of the TRPV6 mutations leading to transient neonatal hyperparathyroidism (OMIM:618188) are loss-of-function mutations spread all over the full-length channel.⁵⁷ The impaired placental TRPV6 mediated Ca^{2+} influx induces fetal hypocalcemia, leading to a secondary hyperparathyroidism where too much parathyroid hormone (PTH) is secreted. The consequence is a metabolic bone disease in affected infants, who present prenatal fractures, malformation of long bones and shortened ribs. In contrast to other TRPV channel-associated diseases where treatment is exclusively symptomatic, post-natal recovery was observed after oral Ca^{2+} supplementation.⁵⁷ These findings underline the importance of the TRPV ion flux fine tuning in respective tissues. TRPV channels can be divided into two groups: thermosensitive and polymodal TRPVs (TRPV1-4), which show a low basal ion channel activity and comparable low Ca^{2+} ion selectivity in comparison to the second group, consisting of TRPV5 and 6. The latter two are Ca^{2+} selective with a constitutive activity and are not ligand-gated. It was shown that calmodulin (CaM) regulates TRPV5 and 6 in a negative, Ca^{2+} -influx dependent feedback loop by blocking the cytosolic side of the ion pore.^{58,59} Regarding the disease severity of TRPV4 gain-of-function mutations, TRPV4 seems to be the wild child amongst the TRPV channels. The tissue-specificity of TRPV4-associated diseases hints towards a vulnerability of these tissues due to the higher TRPV4-mediated Ca^{2+} -influx. Systemic antagonism of TRPV4 with the highly selective TRPV4 antagonist HC-067047 in mice lead to no severe side effects regarding parameters like motor coordination, fluid intake, heart rate and thermoregulation.⁶⁰ Additionally, the orally available, highly selective TRPV4 antagonist GSK2798745 was recently examined in a phase I clinical trial in healthy subjects and patients with cardiogenic pulmonary edema (NCT02119260). TRPV4 plays a central role in pulmonary capillary endothelium, where the ion channel has a critical role in the development of high pulmonary venous pressure (PVP)-associated lung edema after heart-failures. Pulmonary capillary endothelial TRPV4 gets activated upon high PVP, leading to a reduced alveolar barrier due to endothelial cell detachment in lungs. As a consequence, the pulmonary capillaries show increased fluid (blood plasma) permeability and this leads ultimately to pulmonary edema.^{61,62} GSK2798745 was well tolerated by healthy subjects and patients in terms of no detectable changes in vital and clinical laboratory parameters. However, pulmonary edema patients showed shortness of breath and reduced exercise tolerance upon GSK2798745 treatment. Nevertheless, the patients did not show disease worsening. GSK2798745 laid therefore the foundation for a possible, future systemic TRPV4-antagonism in human diseases.⁶¹ As *trpv4* null mice just show mild phenotypes as mentioned above and systemic, pharmaceutically administrated TRPV4 antagonism seems to be well tolerated in mice and humans, it

is hypothesized that TRPV4-mediated Ca^{2+} -influx can be compensated with other ion channels (or in the case of TRPV6-associated neonatal hyperparathyroidism even with nutritional supplementation), but uncontrolled Ca^{2+} -influx leads to pathophysiological consequences in disease-related tissues. Several mechanisms were proposed, coupling TRPV4 mutations with disease pathology, like calcium-induced cell death or altered neuritogenesis.³¹ But ultimately, all these hypotheses aim towards either altered gene expression, probably through a Ca^{2+} /CaM-dependent pathway or altered protein-protein interactions between TRPV4 and cell-type specific protein complexes. Especially for the neuropathy-causing mutations, which mainly cluster in the cytosolic TRPV4 N-terminus, altered tissue-specific PPIs could be the reason for the neurospecificity of these mutations.

1.3 Human TRP channels and their protein networks - glimpses of a brave new world

In the last decades, several high-throughput methods to identify protein interactomes emerged and were optimized continuously, such as protein-fragment complementation assay screens (PFCAs) like the yeast two-hybrid assay (Y2H) or mass spectrometry (MS) approaches. PFCAs map binary PPIs in the context of defined libraries of probable interactors, whereas MS approaches can provide qualitative and quantitative information of PPIs in complex protein networks.^{63,64} The characterization of ion channel interactomes with MS-based proteomics greatly contributed to a better understanding of these supramolecular complexes, like for the glutamate receptors of the AMPA-type (AMPA receptors).⁶⁵⁻⁶⁷ AMPARs are cation channels localized in the central nervous system, where they are involved in signal transmission in glutamatergic synapses. AMPARs are activated by the neurotransmitter glutamate, but also by the synthetic glutamate analog AMPA.⁶⁷ Based on classical molecular cloning, AMPARs were assumed to consist of four GluA transmembrane proteins, which are surrounded by up to four auxiliary subunits, which are either the so called transmembrane AMPAR regulatory proteins (TARPs), chornichon homologs or the GSG1-I protein. However, comprehensive MS-based proteomics revealed that AMPARs are more complex supramolecular constructs which assemble from a pool of 34 proteins known to date. From these 34 proteins, 21 were newly identified via MS, underlining the strength of unbiased and hypothesis-free MS-based proteomics. Such MS-based approaches provide roadmaps for further in-depth and structural investigations of the molecular

framework for the highly complex cell physiology of not only AMPARs, but also other ion channels.

Surprisingly, human TRP channel PPIs listed in table 6.1 were either determined via fusion protein-pull down assays with subsequent western blotting or classical Y2H assays. Only for two human TRP channels, namely TRPM4 and TRPV4, MS-based human protein interactome studies are published to date, both conducted in HEK293T cells. For human TRPM4, Caceres *et al.* identified proteins with actin cytoskeleton-related functions as the largest group of putative TRPM4 interactors, whereat McCray *et al.* identified a more diverse range of protein as putative TRPV4 interactors, with the small GTPase RhoA as one of the most significant ones (see also section 4.4 for a more detailed description of this PPI).^{68,69} Both approaches were performed with transiently transfected HEK293T cells, expressing the respective full-length channel fused with an affinity tag. This affinity tag enables the purification of the tagged (bait) protein from a cell extract via affinity enrichment, co-purifying putative interactors which are then identified by mass spectrometry.⁶⁴ While this approach provides information about the putative interactome of the full-length channels, it is not possible to determine the exact interaction sites of the putative interactors within the channel. The other known (mostly rodent) TRPV4 interactors were mainly determined with non MS-based approaches like Y2H or co-immunoprecipitations (co-IPs) and can be mainly divided into three categories (for a list extracted from the TRIP database see table 6.2). First category comprises cytoskeletal and cytoskeletal associated proteins like α -arrestin 1-2, tubulins, α -actin and PACSIN1-3, indicating TRPV4s role in mechanosensitivity.^{70,71} The second category includes interactors which modify TRPV4 post-translationally, like the tyrosin-kinases LYN and FYN or the E3 ubiquitin ligase ITCH. The third category includes transmembrane proteins like other TRP channels or AQP-4, for example. Most of the co-IPs were combined with site-directed mutagenesis to identify the exact TRPV4 interaction site, like for one of the most prominent TRPV4 interactors PACSIN3.^{70,71} Whereat approaches like before mentioned co-IPs with site directed mutagenesis of probable interaction sites are able to provide information about direct PPIs, the restriction to binary PPI studies compromises the speed but also an comprehensive overview of putative supramolecular complexes. Overall, little is known about the TRPV4 protein interactome. To get a comprehensive, unbiased overview of a complex proteome or interactome, the highly sophisticated ultra high-definition mass spectrometry^E (UDMS^E) - first presented by Distler *et al.* - is the method of choice.⁷² Shortly described, UDMS^E increases drastically the number of identified peptides in a complex mixture by introducing collision-energy dependent traveling wave-based ion-mobility separation (CE-dependent IMS) into liquid-chromatography coupled mass spectrometry (LC-

MS). With this, the precursor ion fragmentation efficiency improves significantly, enhancing the analytical depth of unbiased data-independent data acquisition.⁷² With this and by additionally developing a robust and comprehensive in-house software for UDMS^E data analysis, named ISOQuant, Distler and Kuharev *et al.* increased the numbers of identifiable protein groups compared to other generic MS set-ups significantly.^{73,74} With this, UDMS^E is an excellent label-free and quantitative method to elucidate the protein interactome of TRPV4, which is involved in several severe channelopathies, as mentioned above. Due to the accumulation of disease-causing mutations in the cytosolic TRPV4 N-terminus (hsV4N), this domain was chosen as a starting point to elucidate the TRPV4 protein interactome in HEK293 cells. The high sensitivity and in-depth protein coverage of UDMS^E is essential for future TRPV4 interactome investigations in TRPV4 channelopathy-affected tissues, as this method is particularly suitable to identify altered tissue-specific protein-protein interactions as a possible reason for the disease pathology and tissue specificity of respective TRPV4 mutations.²⁷ Therefore, UDMS^E results serve as an excellent guidance for further in-depth investigations of determined TRPV4 interactome members.

1.4 Aim of this thesis - taming the wild child TRPV4

The TRPV4 N-terminus is a notorious hot-spot of disease-causing mutations, which mostly result in gain-of-function ion channels and dysregulated Ca²⁺-influx.^{49,53,54} Interestingly, especially the N-terminus harbors a significant amount of mutation sites which cause peripheral neuropathies like Charcot-Marie-Tooth Type 2C (CMT2C).^{54,56,75} As the TRPV4 N-terminus consists of important protein interaction sites like the ankyrin repeat domain (ARD) or the proline rich region (PRR) and due to its cytosolic protrusion, this thesis elucidates the PPIs of the human (mutated) TRPV4 N-terminus (hsV4N) with a multipronged approach *in vitro* and *in cellulo*. For this, a major focus of this thesis was to elucidate the overall HEK293 cell protein interactome of hsV4N via ultra high-definition mass spectrometry^E (UDMS^E) and to narrow down the interaction sites by conducting identical UDMS^E experiments with the isolated TRPV4 ARD (hsV4 ARD). After data evaluation and protein-protein network analysis via gene ontology enrichment (GO), for example, promising interaction candidates were worked out. Possible direct interactions between hsV4N and respective candidates were then investigated with a versatile spectrum of methods, spanning from *in cellulo* experiments like live Ca²⁺-imaging, co-immunoprecipitations and fluorescence microscopy to the very detailed elucidation of PPIs with

nuclear magnetic resonance spectroscopy and cross-linking mass spectrometry. Ultimately, this thesis laid the foundation to understand the tissue specific disease outcomes of TRPV4 mutations and for possible future regulations of the pathological Ca^{2+} -influx, which is especially interesting for the progressive motoneuron-degeneration in CMT2C.

2 Materials

2.1 Chemicals

Table 2.1: Chemicals

Chemical	Supplier
Acetic acid 100 % (AcOH)	Roth, Karlsruhe
Acrylamide/Bisacrylamide 37.5 %	Roth, Karlsruhe
Acetonitrile LC-MS grade (ACN)	Roth, Karlsruhe
¹⁵ N-Ammonium chloride (¹⁵ NH ₄ Cl)	CIL Inc., Tewksbury (USA)
Ammonium peroxisulfate (APS)	Roth, Karlsruhe
Adenosinediphosphate (ADP)	Roth, Karlsruhe
Adenosinetriphosphate (ATP)	Roth, Karlsruhe
Agar Agar	Roth, Karlsruhe
Agarose	Roth, Karlsruhe
Ampicillin sodium salt (Amp)	Roth, Karlsruhe
L-Ascorbic Acid	Sigma-Aldrich, Munich
D-Biotin	Roth, Karlsruhe
Dynabeads TM M-280 Streptavidin	Invitrogen, Darmstadt
Dynabeads TM Protein G	Invitrogen, Darmstadt
Bovine serum albumin (BSA)	Roth, Karlsruhe
Benzamidine hydrochlorid	Sigma-Aldrich, Munich
Bromphenol blue sodium salt	Roth, Karlsruhe
3-[(3-Cholamidopropyl)dimethylammonio]-1-propanesulfonate (CHAPS)	Roth, Karlsruhe
Coomassie Brilliant Blue G-250 Dye	Roth, Karlsruhe
Coomassie Brilliant Blue R-250 Dye	Roth, Karlsruhe

Chemical	Supplier
Calcium chloride (CaCl ₂)	Roth, Karlsruhe
CHS (Cholesteryl hemisuccinate)	Sigma Aldrich, Munich
Digitonin	Roth, Karlsruhe
Dithiothreitol (DTT)	Sigma-Aldrich, Munich
Dimethylsulfoxide (DMSO), Headspace Grade or BioScience-Grade	Roth, Karlsruhe
4',6-diamidino-2-phenylindole (DAPI)	Sigma-Aldrich, Munich
Ethanol 99.9 % p.a. (EtOH)	Roth, Karlsruhe
Ethidium bromide 99.9 %	AppliChem, Darmstadt
Formic acid Optima LC/MS (FA)	Thermo Scientific, Waltham (USA)
Fura 2-AM	Invitrogen, Darmstadt
Glycerol	Roth, Karlsruhe
D-Glucose	Roth, Karlsruhe
GSK-1016790A (GSK-101, TRPV4 agonist)	Sigma-Aldrich, Munich
HC-067047 (HC-067, TRPV4 antagonist)	Sigma-Aldrich, Munich
4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES)	Sigma-Aldrich, Munich
Hydrochloric acid (HCl)	Roth, Karlsruhe
Isopropyl- β -D-thiogalactopyranoside (IPTG)	Roth, Karlsruhe
Isopropyl alcohol	Roth, Karlsruhe
Imidazol	Roth, Karlsruhe
Kanamycin sulphate	Roth, Karlsruhe
Lipofectamin LTX	Invitrogen, Darmstadt
Methanol 99.9 % p.a. (MeOH)	Roth, Karlsruhe
Magnesium chloride hexahydrate (MgCl ₂ ·6 H ₂ O)	Roth, Karlsruhe
Magnesium sulfate heptahydrate (MgSO ₄ ·7 H ₂ O)	Roth, Karlsruhe
Mowiol® 4-88	Sigma-Aldrich, Munich
n-Dodecyl β -D-maltoside (DDM)	Sigma-Aldrich, Munich
β -nicotinamide adenine dinucleotide (NADH)	Sigma-Aldrich, Munich
Nickel nitrilotriacetic acid (Ni ²⁺ -NTA) agarose	QIAGEN, Hilden
Paraformaldehyde (PFA)	Sigma-Aldrich, Munich
Pierce™Lysis Buffer	Invitrogen, Darmstadt
CST Protease/Phosphatase Inhibitor Cocktail (100X)	CST, Danvers (USA)

Chemical	Supplier
Precision Plus Protein™ Dual Color Standards	BioRad, Hercules (USA)
Phalloidin-TRITC	Sigma-Aldrich, Munich
Potassium ethylenediaminetetraacetic acid (K-EDTA)	Roth, Karlsruhe
Potassium hydroxide (KOH)	Roth, Karlsruhe
Phenylmethylsulfonylfluoride (PMSF)	Sigma-Aldrich, Munich
Phosphoenolpyruvate (PEP)	Sigma-Aldrich, Munich
Potassium chloride (KCl)	Roth, Karlsruhe
PIPES (piperazine-N,N'-bis(2-ethanesulfonic acid))	Roth, Karlsruhe
Roti®-Lumin 1 and 2	Roth, Karlsruhe
SIGMAFAST Protease Inhibitor	
Cocktail Tablet, EDTA-Free	Sigma-Aldrich, Munich
Sodium chloride (NaCl)	Roth, Karlsruhe
Sodiumdodecylsulfate (SDS)	Roth, Karlsruhe
Sodium hydroxide (NaOH)	Roth, Karlsruhe
Sucrose	Roth, Karlsruhe
Tetramethylethylenediamine (TEMED)	Roth, Karlsruhe
Tris(hydroxymethyl)aminomethane (Tris)	Roth, Karlsruhe
Triton X-100	Roth, Karlsruhe
Tween® 20	Roth, Karlsruhe
Water, HPLC gradient grade	Roth, Karlsruhe
Water, LC-MS grade	Roth, Karlsruhe

2.2 Buffer and solutions

Table 2.2: General buffer and solutions

Buffer/solution	Ingredients
10x Running buffer pH = 8.3	20 mM Tris 1.54 M Glycin

Buffer/solution	Ingredients
1x SDS-PAGE-Running buffer pH = 8.3	1x Running buffer 0.1 % (v/v) SDS

Buffer/solution	Ingredients
TEV dialysis buffer	50 mM Tris-HCl pH = 8 5 % (v/v) Glycerol 200 mM NaCl 50 mM Tris-HCl pH = 8 1 mM DTT TEV: ITCH 1 : 30 molar ratio
Reverse IMAC	10 mM Imidazol pH = 8 200 mM NaCl 50 mM Tris-HCl pH = 8 5 % (v/v) Glycerol
SEC buffer	200 mM NaCl 50 mM Tris-HCl pH = 8

Table 2.8: Buffer and solutions for purification of TRPC 3, 4 and 6 ARDs

Buffer/solution	Ingredients
<i>E.coli</i> lysis buffer TRPC ARDs	20 mM Imidazol pH = 8 300 mM NaCl 20 mM Tris-HCl pH = 8 0.1 % (v/v) Triton X-100 add fresh: 1 mM Benzamidine 1 mM PMSF 1 SIGMAFAST Protease Inhibitor RNase, DNase, Lysozyme
IMAC Wash 1	20 mM Imidazol pH = 8 300 mM NaCl 20 mM Tris-HCl pH = 8
Wash 2	50 mM Imidazol pH = 8 300 mM NaCl

Buffer/solution	Ingredients
Elution	20 mM Tris-HCl pH = 8
	500 mM Imidazol pH = 8
	300 mM NaCl
SEC buffer	20 mM Tris-HCl pH = 8
	10 mM Tris-HCl pH = 7
	1 mM K-EDTA pH = 7
	300 mM NaCl
	1 mM DTT
	1 mM Benzamidine

Table 2.9: Buffer and solutions for purification of hsYAP-WW domains

Buffer/solution	Ingredients
<i>E. coli</i> lysis buffer hsYAP WW domains	20 mM Imidazol pH = 7.4
	120 mM NaCl
	30 mM HEPES pH = 7.4
	0.1 % (v/v) Triton X-100
	add fresh:
	1 mM Benzamidine
	1 mM PMSF
	1 SIGMAFAST Protease Inhibitor
IMAC Wash 1	RNAse, DNase, Lysozyme
	20 mM Imidazol pH = 8
	120 mM NaCl
IMAC Wash 2	30 mM HEPES pH = 8
	50 mM Imidazol pH = 8
	120 mM NaCl
IMAC Wash 3	30 mM HEPES pH = 8
	75 mM Imidazol pH = 8
	120 mM NaCl

Buffer/solution	Ingredients
IMAC Elution	30 mM HEPES pH = 8 500 mM Imidazol pH = 8 120 mM NaCl
TEV dialysis buffer	30 mM HEPES pH = 8 300 mM NaCl 25 mM Tris-HCl pH = 7 1 mM DTT TEV: hsYAP-WW domains 1 : 30 molar ratio
Reverse IMAC buffer	10 mM Imidazol pH = 8 120 mM NaCl
SEC buffer	30 mM HEPES pH = 8 120 mM NaCl 30 mM HEPES pH = 7.4

2.3 Enzymes

Table 2.10: Enzymes

Enzymes	Supplier
Desoxyribonuclease I (DNase)	Sigma-Aldrich, Munich
DpnI	NewEngland BioLabs, Frankfurt a.M.
HiFi Polymerase	Kapa Biosystems, Wilmington (USA)
Lactate Dehydrogenase (LDH)	Sigma-Aldrich, Munich
Lysozyme	Sigma-Aldrich, Munich
Ribonuclease A (RNase)	Sigma-Aldrich, Munich
T5 Exonuclease	NewEngland BioLabs, Frankfurt a.M.
Phusion DNA Polymerase	NewEngland BioLabs, Frankfurt a.M.
Pyruvate Kinase (PK)	Sigma-Aldrich, Munich
Taq DNA Ligase	NewEngland BioLabs, Frankfurt a.M.

Enzymes	Supplier
E1 Ubiquitin ligase UBE1	Prof. Sumner, Baltimore (USA)
E2 Ubiquitin ligase Ubc5Hc	Prof. Sumner, Baltimore (USA)

2.4 Antibodies

Table 2.11: Antibodies

Antibody	Supplier
Anti-ANXA2 mouse	Sigma-Aldrich, Munich
Anti-DDX3X rabbit	Sigma Aldrich, Munich
Anti-GFP mouse (3E6)	Invitrogen, Darmstadt
Anti-GFP mouse	Sigma-Aldrich, Munich
Anti-FLAG mouse	CST, Danvers (USA)
Anti-FLAG rabbit	CST, Danvers (USA)
Anti-V5 mouse	CST, Danvers (USA)
Anti-myc mouse	CST, Danvers (USA)
Anti-His ₆ -HRP	Invitrogen, Darmstadt
Streptavidin-POD (Strep-POD)	Roche, Basel (CH)
Horse anti-mouse HRP-linked IgG	CST, Danvers (USA)
Goat anti-rabbit HRP-linked IgG	CST, Danvers (USA)
Alexa-Fluor-488 goat anti-mouse	Invitrogen, Darmstadt
Alexa-Fluor-555 goat anti-rabbit	Invitrogen, Darmstadt
Alexa Fluor-647 goat anti-mouse	Invitrogen, Darmstadt
Alexa Fluor-647 goat anti-rabbit	Invitrogen, Darmstadt

2.5 Oligonucleotides

The oligonucleotides in tables 2.12 and 2.13 were designed in the course of this work and were obtained from Sigma-Aldrich (Munich). For the estimation of the melting temperatures equation 2.1 was used. The nomenclature of the primers refers to the employed nomenclature at the Hellmich workgroup.

$$T_m = 4 \cdot \#G \text{ and } C + 2 \cdot \#A \text{ and } T \quad (2.1)$$

2.6 Plasmids and expression constructs

T7_oligonucleotides (table 2.14) were used to determine the DNA sequence of the various modified pET21, pET28a, pET11 and pcDNA3.1 plasmids (table 2.14). For reverse sequencing of pcDNA3.1 the SP6 oligonucleotide was used. mm = *Mus musculus* (mouse), hs = *Homo sapiens* (human), gg = *Gallus gallus* (chicken), rn = *Rattus norvegicus* (rat), d = *Drosophila melanogaster* (fruit fly), dr = *Danio rerio* (zebra fish).

Table 2.15: Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.

2.7 Peptide and protein characteristics

In the following, protein and peptide characteristics of the constructs used in this work are listed. Table 2.16 lists all constructs which were recombinantly expressed in *E. coli* BL21 Gold (DE3) cells and subsequently purified according section 3.7. Characteristics of protein and peptides with no TEV-cleavage site are listed with the His₆-tag, whereas TEV cleavage site containing proteins are listed without His₆-tag.

Table 2.17 lists all protein construct which were recombinantly expressed in HEK293 and/or HEK293T cells (see also sections 3.2.1, 3.3, 3.4 and 3.5).

Table 2.16: Physicochemical properties of proteins and peptides recombinantly expressed in *E. coli* BL21 Gold (DE3), purified and used in this thesis. Characteristics were calculated using the ProtParam tool (<http://web.expasy.org/protparam/>). hsV4N Δ 132 is also referred to as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. MW: molecular weight [Da]; AA: number of amino acids; pI: isoelectric point; ϵ 280: extinction coefficient at 280 nm in [L mol⁻¹ cm⁻¹]

3 Methods

3.1 General methods

3.1.1 Heat-shock transformation of *E. coli* bacteria

0.5 μ L of plasmid DNA were added to 25 μ L of competent *E. coli* BL21 (DE33) Gold or DH5 α cells and incubated on ice for 30 min. Cells were heat shocked at 42 °C for 45 s and again incubated on ice for 2 min. Afterwards, 300 μ L of LB-Medium were added and the cells were grown for 1 h at 37 °C and 225 rpm. Subsequently, the cells were plated onto an antibiotic containing agar plate and incubated over night at 37 °C.

3.1.2 Plasmid DNA preparation from *E. coli*

An over night culture of *E. coli* DH5 α cells was cultivated in 5 mL LB medium at 37 °C which contained the suitable amount of antibiotics. After centrifugation at 3900 rpm for 10 min at 4 °C the plasmid DNA was isolated with the E.Z.N.A Plasmid Mini Kit I (protocol I of instruction manual). DNA concentration was determined by absorption measurements at 260 nm with a ThermoScientific NanoDrop 2000c UV-Vis spectrophotometer.

3.1.3 Polymerase chain reaction (PCR)

Modifications and amplifications of DNA fragments were performed via PCR. For this the Kapa HiFi HotStart PCR Kit and a Primus 25 thermo cycler were used. For more details on used oligonucleotides and methods see subsection 3.1.4 and tables 2.13 and 2.12. Prior to further usage, the template DNA was digested with DpnI, which specifically recognizes methylated

DNA. Furthermore the DNA was cleaned up with the GenepHlow Gel/PCR Kit and eluted in 30 μL ddH₂O.

Table 3.1: DpnI digestion reaction mixture

Component	Volume [μL]
10x Cutsmart buffer	5
ddH ₂ O	22.5
DpnI	1
PCR reaction mixture	22.5

3.1.4 Gibson Assembly

Gibson Assembly is a suitable method to merge linear DNA fragments to obtain, for example, new combinations of insert and vector DNA.^{79,80} After generation of linear DNA segments via PCR, annealing of the fragments is performed in a buffer which contains three different enzymes. First, an exonuclease creates single-stranded 3' overhangs for annealing purposes. The occurring gaps in the annealed DNA fragments are filled by a DNA polymerase and a DNA ligase covalently links the fragments. After incubation of the DNA fragments in the isothermal ligation reaction mix (see table 3.2) for 1 h at 50 °C, the DNA was transformed into *E. coli* DH5 α cells and isolated as described in sections 3.1.1 and 3.1.2.

Table 3.2: Reaction mixtures for Gibson Assembly

Buffer/solution	Ingredients
5x Isothermal Reaction Mix	0.5 M Tris-HCl pH = 7.5 0.5 M MgCl ₂ 1 mM dNTP Mix 0.25 g/mL PEG-8000 0.5 M NAD ⁺
Assembly Master Mix	1x Isothermal Master Mix

Buffer/solution	Ingredients
	0.5 U/ μ L T5 Exonuclease
	0.3 U/ μ L Phusion DNA Polymerase
	0.5 U/ μ L Taq DNA Ligase

3.1.5 Agarose gel electrophoresis

To separate DNA with various sizes agarose gel electrophoresis was performed. 1 or 2% (w/v) agarose gels were used. Visualization of the different DNA plasmids and fragments was achieved by ethidium bromide staining for at least 20 min and detection with UV-light.

3.1.6 DNA sequencing

To confirm successful cloning of genes, DNA sequencing was performed by *GENterprise GENOMICS* (StarSEQ GmbH, Mainz). The primers from table 2.14 were used. The final sequencing mixture contained 300 - 700 ng plasmid DNA and 1 μ L sequencing primer (10 μ M stock solution, see also table 2.14) topped up to a total volume of 7 μ L with ddH₂O.

3.1.7 SDS polyacrylamide gel electrophoresis (SDS-PAGE)

Proteins were separated according to their molecular weight with SDS-PAGE. For buffer compositions see table 2.2. Amongst other methods (see also section 3.1.8), visualization of the protein bands were accomplished by Coomassie staining. For the compositions of the Coomassie staining and destaining solution also see table 2.2.

Table 3.3: Composition of the stacking and separation gel for SDS-PAGE

Ingredients	separation gel 15%	separation gel 12%	stacking gel
ddH ₂ O	4.6 mL	4.6 mL	4.6 mL
1.5 mM Tris-HCl pH 8.8	5 mL	5 mL	/

Table 3.3: Composition of the stacking and separation gel for SDS-PAGE

Ingredients	separation gel 15 %	separation gel 12 %	stacking gel
1.0 mM Tris-HCl pH 6.8	/	/	0.63 mL
Acrylamid/Bisacrylamid 30 %	10 mL	8 mL	0.83 mL
SDS 10 % (w/v)	0.2 mL	0.2 mL	0.5 mL
APS 10 % (w/v)	0.2 mL	0.2 mL	0.5 mL
TEMED	0.2 mL	0.2 mL	0.5 mL

3.1.8 Western blot and chemiluminescence detection

After SDS-PAGE (see section 3.1.7) separated proteins were transferred onto a PVDF membrane with another electrophoresis step to detect specific proteins and/or their modifications, respectively, with an antibody mediated chemiluminescence reaction. Depending on the used antibodies, the membrane was incubated in different blocking solutions for 1 h at room temperature (see also 3.4). After three wash steps, each for 5 min at room temperature with PBS/T, the membrane was incubated in the particular peroxidase-coupled antibody solution (see also 3.5). Again, three wash steps were performed and chemiluminescence was induced with a 1:1-mixture of Roti®-Lumin reagents 1 and 2 detected either with a STELLA 3200 or GE Image-Quant CCD camera.

Table 3.4: Used primary antibody solutions and blocking solutions

Antibody solution	Blocking solution (% in w/v)
Anti-His ₆ -HRP 1:5000 in 2 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Strep-POD 1:20 000 in 1 % (w/v) BSA in PBS/T	2 % (w/v) BSA in PBS/T
Anti-ANXA2 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Anti-DDX3X 1:1000 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Anti-V5 mouse 1:5000 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Anti-myc mouse 1:1000 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Anti-FLAG rabbit 1:1000 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T
Anti-FLAG mouse 1:1000 in 1 % (w/v) milk powder in PBS/T	5 % (w/v) milk powder in PBS/T

Table 3.5: Used secondary antibody solutions

Antibody solution
Horse anti-mouse HRP-linked IgG 1:1000 in PBS/T
Goat anti-rabbit HRP-linked IgG 1:1000 in PBS/T

3.1.9 Protein quantification

To determine the protein concentrations various methods were used.

Bradford assay

With the Bradford Assay it is possible to obtain the concentration of protein in a sample via the quantitative assessment of the absorbance shift of Coomassie G-250 based on interactions between dye and proteins. As standards, increasing concentrations of BSA solutions were used (0 to 200 $\mu\text{g}/\mu\text{L}$).

Absorption measurements

Another method to assess the protein concentration of a sample is to measure the absorption at 280 nm with a ThermoScientific NanoDrop 2000c UV-Vis spectrophotometer due to the absorption of aromatic amino acids (tyrosine, tryptophan, phenylalanine). Because the number of these aromatic amino acids are varying in each protein, the specific molar extinction coefficients at 280 nm were computed using the ExPasy-ProtParam tool (<http://web.expasy.org/protparam/>).

3.1.10 Size exclusion chromatography

Proteins were purified according to their size via size exclusion chromatography (SEC). Depending on the sample volume and protein size, various columns were used (see table 3.6)

Table 3.6: Used SEC columns, manufactured by GE Healthcare

Column name	column volume	sample volume	separation range
HiLoad 16/600 Superdex 200	120 mL	≤ 5 mL	70 000 - 3000 Da
HiLoad 16/600 Superdex 75	120 mL	≤ 5 mL	600 000 - 10 000 Da
Superose™ 6 10/300 GL	24 mL	≤ 500 μ L	5 000 000 - 5000 Da

Columns were stored at 4 °C in 20 % (v/v) ethanol. SEC runs for each protein were also carried out at 4 °C and the columns were equilibrated in the appropriate SEC buffer before every protein purification. Chosen protein samples were adjusted to the desired sample volume with a centrifugal concentrator. Potential aggregates were removed by centrifugation at 3900 rpm and 4 °C for 10 min before loading it onto the SEC column. The sample was loaded onto a suitable loop and injected onto the column with a flow rate of 0.5 mL/min. Elution was performed isocratically for 1.1 CV. The flow rates during elution as well as the collected fraction size were adjusted to the individual proteins (see 3.7). The absorbance at 280 nm was detected and the purity of collected fractions verified via SDS-PAGE with subsequent Coomassie staining.

3.2 Cell culture of eukaryotic cells

3.2.1 Cultivation

HEK293 cell strains (see table 2.20) were cultivated in 10 cm dishes at 37 °C, 5 % CO₂ atmosphere and 95 % humidity with DMEM containing 10 % (v/v) FCS, 1 % (v/v) P/S and 1 % (v/v) L-Glutamine. HEK293-hsV4-cGFP were additionally treated with 0.500 μ g/mL G-418 and 200 nM

TRPV4 inhibitor HC-067, HEK293-hsTRPML1-nGFP cells with 0.375 µg/mL G-418. Twice a week the cells were splitted in a ratio of 1:8. For splitting, the expended medium was aspirated and the cells were washed with 5 mL PBS. Afterwards, the cells were trypsinized with 1.5 mL trypsin/EDTA in 1.5 mL PBS and diluted to the desired ratio with fresh medium. The cells were then plated on fresh dishes. All media were warmed up to 37 °C in a water bath before use.

3.2.2 Transient transfection of HEK293T cells

For transient transfection of HEK293T cells, 575 000 cells were seeded into 6-well plates per well 24 h before transfection. Cells were transfected according the Lipofectamin® LTX reagent protocol. For fluorescence microscopy (see section 3.3) and live calcium imaging (see 3.5) poly-L-lysinated cover slips were provided in the 6-well dish. Used plasmid DNAs are listed in table 2.15 and used plasmid DNA amounts for transfections in table 3.7. If not otherwise indicated, cells were incubated with the DNA/lipid complex for 24 h.

Table 3.7: Used plasmid DNA amounts for transfections of HEK293T cells with Lipofectamine® LTX

3.2.3 Stable transfection of HEK293 cells

To generate stable HEK293 cell lines stably expressing either hsTRPV4-cGFP or hsTRPML1-nGFP, HEK293 cells were transfected as previously described (see 3.2.2). For used plasmid DNA amounts, see table 3.8. Furthermore, after transfection, HEK293 cells expressing hsTRPV4-cGFP (HEK293-hsV4-cGFP), if not otherwise indicated, were always treated with 200 nM of the TRPV4 antagonist HC-067.

Table 3.8: Used plasmid amounts for stable transfections of HEK293 cells with Lipofectamine® LTX

Expressed construct	Vector	Plasmid DNA amount [ng/well]	G-418 amount [$\mu\text{g}/\mu\text{L}$]
hsTRPV4-cGFP	pcDNA3.1-cGFP	500	0.500
hsTRPML1-nGFP	pEGFP C3	2000	0.375

After 24 h incubation with the DNA/lipid complex, cells were examined for GFP-signals on a widefield Zeiss Axio Observer Z1 Inverted Microscope. If GFP-positive, cells were passaged for 2 weeks and selected with G-418 (see table 3.8), with G-418-containing media changes after every 48 h. Large, healthy and GFP-positive colonies were isolated with sterile tooth-picks and cultured for another 3 weeks in G-418 medium with media changes after every 48 h. With this, stably expressing, polyclonal cell lines were obtained. Proper protein expression, function and localization were confirmed with Western Blots with subsequent chemiluminescence detection, fluorescence microscopy and Ca^{2+} -influx assays. Generation of monoclonal cell lines failed, as the single cell transfer into 96-well plates resulted multiple times in cell death.

3.3 Immunostaining and fluorescence microscopy

HEK293T or HEK293 cells were stably or transiently transfected with plasmid DNA encoding for the desired protein (see sections 3.2.2 and 3.2.3). To obtain insights in protein localization and protein-protein co-localization in cells, immunostaining was performed on the cells. Cells were washed three times with PBS containing 0.2 % (v/v) Tween®-20 (PBS/T), followed by an incubation step with 50 mM NH_4Cl in PBS for 10 min due to formaldehyde quenching. To permeabilize the cell membranes towards the staining antibodies or reagents, the cells were incubated in PBS containing 0.3 % (v/v) Triton-X for 15 min at RT and washed with PBS for 3 times. After discarding, the cells were incubated in 1 % (w/v) BSA in PBS/T for 30 min and washed with PBS/T for three times. If needed, primary antibodies diluted in 1 % (w/v) BSA in PBS/T (see table 3.9) were applied to the cells and incubated at 4 °C over night. After washing with PBS/T for three times, respective secondary antibodies in PBS/T were applied and incubated for 1 h

at RT. Again three washing steps with PBS/T were performed. For F-actin staining, cells were incubated for 1 h with Phalloidin-TRITC at RT and after 3 PBS/T washing steps, nuclei were stained with DAPI for 30 min at RT. The cells were washed again for three times with PBS/T and finally with pure PBS. The cell bearing cover slips were mounted on microscopic slides with Mowiol® 4-88 and kept in the dark until further usage.

Table 3.9: Antibodies used for cell immunostainings

Antibody	Amount [$\mu\text{g}/\text{mL}$]
Anti-ANXA2 mouse	2
Anti-DDX3X rabbit	2
Anti-FLAG rabbit	2
Anti-V5 mouse	2.5
Anti-myc mouse	2
Alexa-Fluor-488 goat anti-mouse	4
Alexa-Fluor-555 goat anti-rabbit	4
Alexa Fluor-647 goat anti-mouse	5
Alexa Fluor-647 goat anti-rabbit	5
Phalloidin-TRITC	50

Fluorescence microscopic images were obtained with a wide field Zeiss Axio Observer Z1 Inverted Microscope, kindly provided by Prof. Gerald Gimpl (Department of Chemistry, Biochemistry Section, Johannes Gutenberg University, Mainz), or a Zeiss LSM800 Confocal Microscope (Microscopy Core Facility, JHU School of Medicine). The obtained pictures were extracted and processed with the biological-image analysis program Fiji.⁸¹

3.4 Co-Immunoprecipitation in eukaryotic cells

Co-Immunoprecipitation (co-IP) is a straight-forward technique to evaluate protein complexes under physiological conditions. In this work, an antibody-based co-IP protocol with protein G-coated magnetic beads was performed. Transfected cells (see sections 3.2.2 and 3.2.3) were

washed three times with ice-cold PBS and then harvested with 1 mL/well of a 6-well plate. Cells were lysed with Pierce™ Lysis Buffer supplemented with CST Protease/Phosphatase-Inhibitor. After two centrifugation steps at 4600 rpm and 13 900 rpm, respectively, for 15 min at 4 °C, the supernatant was transferred in a fresh, pre-chilled tube. The Protein G-coupled beads were coated with respective antibody for 15 min at RT and then were washed one time with PBS/T. After this, the antibody-coated beads were incubated with the supernatant for 2 h at 4 °C under mild rotation. Beads were then washed three times with PBS/T and finally, proteins were eluted from the beads with 1x SDS-PAGE sample buffer (see table 2.2) at 70 °C for 10 min. Samples then were subjected to SDS-PAGE and western blotting with subsequent chemiluminescence detection (see sections 3.1.7 and 3.1.8).

3.5 Live Ca²⁺ imaging

Live calcium imaging (Ca²⁺ imaging) was performed on a Zeiss Axio Observer Z1 inverted microscope equipped with a Lambda DG-4 wavelength switcher. 24 h prior treatment, 6.8x10⁵ cells/well were seeded into a 6-well plate, provided with Poly-L-coated cover slips in each well. 1 h prior treatment and Ca²⁺ imaging, cells were loaded with 2.5 μM Fura2 AM for 60 min at 37 °C. For hypotonic treatment, three volumes of hypotonic aCSF (see 2.2) was added to one volume of aCSF (see table 2.2 for buffer composition). For GSK-101 treatment, GSK-101 was added directly to the aCSF buffer. Cells were imaged every 10 seconds for 1 min prior to stimulation with hypotonic saline or GSK-101, then imaged every 10 seconds for an additional 8 min. Calcium levels at each time point were computed by determining the ratio of Fura-2 AM emission at 380 nm divided by the emission at 340 nm. Data are representing raw the Fura ratio.

3.6 Ca²⁺ influx assay

To assure the functionality of stably transfected human TRPV4-cGFP (see also section 3.2.3), fluorescence-based Ca²⁺ influx assays were performed with the Fluo-4 Direct Calcium Assay on a FlexStation 3 MultiMode Plate Reader. Poly-L-lysinated 96-well plates were seeded with 40 000 cells/well and after 24 h, cells were loaded with Fluo-4 Direct™ calcium reagent loading

solution according to the manufacturers protocol. After incubation for 1 h at RT, 5 % CO₂ atmosphere and 95 % humidity, cells were treated with 30 nM GSK-101 end concentration. Resulting fluorescence signals were measured every 3 s for 3 min at RT with an excitation wavelength at 494 nm, an emission wavelength 516 nm and a bandwidth of 1 nm.

3.7 Recombinant expression and purification of constructs

3.7.1 Recombinant expression of human N-terminal TRPV4 (hsV4N) constructs

E. coli BL21 (DE3) Gold cells were heat-shock transformed (see section 3.1.1) with the respective plasmid (see table 2.15). In an over night incubation at 37 °C and 225 rpm a preculture in 50 mL LB medium containing 100 µg/mL ampicillin was set up. Subsequently, 1 L TB medium with 0.2 % (v/v) glucose or LB medium were supplemented with 100 µg/mL ampicillin and inoculated with 2 % (v/v) of preculture. The cells were then grown at 37 °C and 225 rpm to an OD₆₀₀ of 0.6. Used IPTG concentrations and conditions for protein expression are listed in table 3.10. The cells were harvested by centrifugation at 5000 rpm and 4 °C for 10 min. After disposing the supernatant, the cell pellet was frozen with liquid nitrogen and stored at –20 °C until further use.

Table 3.10: Expression conditions of human N-terminal TRPV4 (hsV4N) constructs. hsV4NΔ132 is also referred to as hsV4 ARD, hsV4NΔ122 as hsV4 ARD-PRR. Avi2 = c-terminal avidin-tag followed by a His₆-tag. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [µM]	Duration [h]	Temp. [°C]
hsV4N-His ₆	TB	150	16	20
hsV4N R232C-His ₆	LB	150	16	20
hsV4N-Avi2	TB	150	16	20
hsV4NΔ122-His ₆	LB	75	16	20
hsV4NΔ132-His ₆	LB	75	18	20
hsV4NΔ132 R232C-His ₆	LB	75	18	20
hsV4NΔ132 R269C-His ₆	LB	75	18	20
hsV4NΔ132 D333G-His ₆	LB	75	18	20
hsV4NΔ132-Avi2	LB	75	16	20

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
hsV4N Δ 132 R232C-Avi2	LB	75	18	20
hsV4N Δ 132 K276E-Avi2	LB	75	18	20
hsV4N Δ 132 V342F-Avi2	LB	75	18	20

The below mentioned purifications were all carried out at 4 $^{\circ}$ C.

3.7.2 Purification of hsV4N constructs

The cell pellet of a 1 L *E. coli* cell culture was suspended in 100 mL *E. coli* lysis buffer (for all buffer compositions see 2.2). Sonification was performed on ice with a Branson Sonifier 250 using a duty cycle of 5 for 50 s. The cell lysate was cleared via centrifugation at 20 000 rpm and 4 $^{\circ}$ C for 40 min. The obtained supernatant was loaded onto 1 mL Ni²⁺-NTA agarose provided in a column which was equilibrated with 2 CV Ni²⁺-NTA buffer 20 beforehand. The flow through was discarded and the Ni²⁺-NTA agarose then washed with 20 CV Ni²⁺-NTA buffer 20, followed by a second and a third wash step with 1 CV Ni²⁺-NTA buffer 50 and 1 CV Ni²⁺-NTA buffer 75, respectively. The His₆-tagged protein was eluted with 9 CV Ni²⁺-NTA buffer 500 and collected in 1 mL fractions, to which 1 mM DTT and 1 mM EDTA were added. Protein purity was analyzed via SDS-PAGE using a 12 % gel. The protein was further subjected to size exclusion chromatography with a HiLoad 16/600 Superdex 200 SEC column, whereas elution was performed over 1.1 CV with SEC buffer hsV4N and collected in 0.5 mL fractions. If necessary, a second SEC with the before purified fractions was performed with SEC buffer hsV4N containing 750 mM NaCl. Purity was analyzed via SDS-PAGE and Coomassie staining.

3.7.3 Purification of hsV4 Δ N122 and hsV4 Δ N132 constructs

hsV4N Δ 132 is also referred to as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The same purification protocol as described in subsection 3.7.2 above was used. The last wash step (W3) was left out, also 10 elution steps with Ni²⁺-NTA buffer 500 were performed. For human RhoA interaction studies via NMR with ¹⁵N-labeled human RhoA (see section 4.4), the SEC of hsV4N Δ 132 R232C-His₆ was performed with the SEC buffer of RhoA (see table 2.4).

3.7.4 Biotinylation and purification of hsV4N constructs

With the insertion of the 15 amino acids containing (GLNDIFEAQKIEWHE) avidin tag (Avi) in the protein of interest it is possible to achieve a specific biotinylation of the desired protein *in vivo* with the *E. coli* biotin ligase BirA. BirA covalently attaches a single biotin to the lysine residue of the avidin tag. The femtomolar affinity constant between biotin and streptavidin can be exploited for further purposes, purification attempts example.⁸² In previous works of the research group Hellmich, an avidin tag was inserted on two different positions in hsV4N and hsV4N Δ N132: either before the C-terminal His₆-tag (hsV4N Avi2) or after the C-terminal His₆-tag (hsV4N Avi3).⁷⁶ For biotinylation of the avidin tagged proteins, *E. coli* BL21 (DE3) Gold cells were heat-shock co-transformed with the respective plasmids, one expressing the BirA ligase (p155) and the other the respective TRPV4 N-terminal construct. Cell cultivation and protein expression were similar as described in section 3.7.1. Additionally, 40 μ M biotin were added to the growth medium to ensure sufficient biotinylation of the target protein.⁸²

Purification of biotinylated human N-terminal TRPV4 constructs

The same purification protocol as described in subsection 3.7.2 above was used with minor deviations. The last wash step (W3) was left out, furthermore 6 elution steps with Ni²⁺-NTA buffer 500 were performed. SEC were executed with a ENrich™ SEC 70 column. Purity was analyzed via SDS-PAGE and Coomassie staining. Successful biotinylation was determined during the purification via dot-blot with a streptavidin-POD (Strep-POD) antibody and also a western blot with the same Strep-POD antibody was performed to verify the correct molecular weight as described previously.^{76,77}

3.7.5 Recombinant expression and purification of human RhoA

The same expression protocol as described in section 3.7.1 was used. Protein expression was induced at an OD₆₀₀ of 0.8. Table 3.11 lists the further expression conditions used for human RhoA in this work.

Table 3.11: Expression conditions of human RhoA. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
human RhoA-His ₆	LB	250	18	16

The same purification protocol as in subsection 3.7.2 was used with buffer conditions suited to human RhoA (see also table 2.4). Furthermore, if needed, a TEV-cleavage was performed overnight to remove the n-terminal His₆-tag (see also table 2.4 for buffer conditions) with subsequent reverse IMAC. Reverse IMAC washing steps were performed until the OD₂₈₀ dropped below 0.4. Concentrated protein containing fractions were then subjected to SEC.

3.7.6 Recombinant expression and purification of human DDX3X_aa122-582 (DDX3X)

The same expression protocol as described in section 3.7.1 was used, but here the used antibiotic was Kanamycin with end concentrations of 50 μ g/mL. Protein expression was induced at an OD₆₀₀ of 0.8. Table 3.12 lists the further expression conditions used for hsDDX3X in this work.

Table 3.12: Expression conditions of hsDDX3X. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
human DDX3X_aa122-582-His ₆	LB	1000	18	25

The same purification protocol as in subsection 3.7.2 was used with buffer conditions suited to hsDDX3X (see also table 2.5). Furthermore, the IMAC was differently performed as described

in the following. The obtained supernatant after cell lysis and centrifugation of 1 L *E. coli* cell culture was loaded onto 3 mL Ni²⁺-NTA agarose provided in a column which was beforehand equilibrated with 2 CV IMAC Wash A buffer. After discarding the flow-through the Ni²⁺-NTA agarose was washed with 15 mL IMAC wash buffer A, followed by 10 mL IMAC High salt buffer and 10 mL IMAC Wash B buffer. Elution steps were performed with IMAC Elution buffer until the OD₂₈₀ dropped below 0.3. Furthermore, if needed, a TEV-cleavage was performed over night to remove the n-terminal His₆-tag (see also table 2.5 for buffer conditions) with subsequent reverse IMAC. Reverse IMAC washing steps were performed until the OD₂₈₀ dropped below 0.2. Concentrated protein containing fractions were then subjected to SEC.

3.7.7 Recombinant expression and purification of human ITCH

The same expression protocol as described in section 3.7.1 was used. Protein expression in the cells were induced at an OD₆₀₀ of 0.8. Table 3.13 lists the further expression conditions used for human ITCH in this work.

Table 3.13: Expression conditions of human ITCH. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
human ITCH-nHis ₆	LB	250	18	16

The same purification protocol as in subsection 3.7.2 was used with buffer conditions suited to human ITCH (see also table 2.6) with the minor deviation during the IMAC, where three times twice the CV was eluted. Furthermore, if needed, a TEV-cleavage was performed over night to remove the n-terminal His₆-tag (see also table 2.6 for buffer conditions) with subsequent reverse IMAC. Reverse IMAC washing steps were performed until the OD₂₈₀ dropped below 0.4. Concentrated protein containing fractions were then subjected to SEC.

3.7.8 Recombinant expression and purification of human ITCH WW domains

The same expression protocol as described in section 3.7.1 was used. Protein expression in the cells were induced at an OD_{600} of 0.8. Table 3.14 lists the further expression conditions used for human ITCH WW domains in this work.

Table 3.14: Expression conditions of human ITCH WW domains. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
hsITCH_WW1 domain-His ₆	LB	250	20	16
hsITCH_WW2 domain-His ₆	LB	250	20	16
hsITCH_WW3 domain-His ₆	LB	250	20	16
hsITCH_WW4 domain-His ₆	LB	250	20	16
hsITCH_WW1+WW2 domains-His ₆	LB	250	20	16
hsITCH_WW3+WW4 domains-His ₆	LB	250	20	16

The same purification protocol as in subsection 3.7.2 was used with buffer conditions suited to human ITCH WW domains (see also table 2.7), with just three elution steps during the IMAC. Furthermore, if needed, a TEV-cleavage was performed over night to remove the n-terminal His₆-tag (see also table 2.6 for buffer conditions) with subsequent reverse IMAC. Reverse IMAC washing steps were performed until the OD_{280} dropped below 0.2. Concentrated protein containing fractions were then subjected to SEC.

3.7.9 Recombinant expression and purification of human YAP-WW domains

The same expression protocol as described in section 3.7.1 was used. Protein expression in the cells were induced at an OD_{600} of 0.8. Table 3.15 lists the further expression conditions used for human YAP WW domains in this work.

Table 3.15: Expression conditions of human YAP WW domains. IPTG conc. = IPTG concentration, Temp. = Temperature

Construct	Medium	IPTG conc. [μ M]	Duration [h]	Temp. [$^{\circ}$ C]
hsYAP1_WW1 domain-His ₆	LB	250	16	20
hsYAP1_WW2 domain-His ₆	LB	250	16	20
hsYAP1_WW1+WW2 domains-His ₆	LB	250	16	20

The same purification protocol as in subsection 3.7.2 was used with buffer conditions suited to human YAP WW domains (see also table 2.9), with just three elution steps during the IMAC. Furthermore, if needed, a TEV-cleavage was performed over night to remove the n-terminal His₆-tag (see also table 2.6 for buffer conditions) with subsequent reverse IMAC. Reverse IMAC washing steps were performed until the OD₂₈₀ dropped below 0.2. Concentrated protein containing fractions were then subjected to SEC.

3.8 Pulldown assay of biotinylated hsV4N constructs

All steps of the below mentioned pulldown assay were carried out at 4 $^{\circ}$ C. HEK293 cells of a 10 cm dish were cultivated until 90 % confluency. After discarding the supernatant, cells were washed once with 5 mL ice-cold PBS and incubated for 10 min in pulldown lysis buffer (see table 2.2) under mild agitation. Due to the short incubation in the digitonin-containing pulldown lysis buffer, the plasma membrane of the HEK293 cells permeabilizes, allowing cytosolic proteins to diffuse into the supernatant of the cells without destroying other cell compartments.⁸³ The supernatant of the still adherent cells was then transferred into a fresh tube and centrifuged for 10 min at 400 rpm. The supernatant again was transferred into a fresh tube and centrifuged for 30_{sec} at 12 000 rpm. The supernatant was transferred into a fresh tube and the protein concentration was determined via a Bradford Assay (see also sec 3.1.9). 20 μ L streptavidin-coated magnetic beads were pre-incubated with 500 ng the respective non- or biotinylated N-terminal TRPV4 protein for 30 min at 4 $^{\circ}$ C under mild rotation. After three washing steps with PBS, the pre-loaded beads were incubated in 250 μ g of the digitonin-extracted HEK293 cytosolic fraction.

To mimic an activation of the TRPV4 cation channel function, some samples were supplemented with 2 mM CaCl_2 . After an incubation for 30 min at 4 °C under mild rotation, beads were washed again three times with PBS and flash-frozen in liquid N_2 until further use.

3.9 Mass spectrometry

Mass spectrometry based proteomics became an indispensable tool for the analysis of proteins and their interaction partners. Several methods have been developed to investigate the complex networks of cell proteomes. In cooperation with Dr. Ute Distler (AG Tenzer, FZI Core Facility for Mass Spectrometry, Mainz) it was possible to approach towards an investigation of the human TRPV4 N-terminus interactome via ultra high-definition mass spectrometry^E (UDMS^E). There are several methods to prepare samples for mass spectrometry. In this work, samples were obtained either after in-gel digestion (see subsection 3.9.1) or in-solution digestion (see subsection 3.9.2) after pulldown experiments with magnetic streptavidin beads (see section 3.8). Digestions (see sections 3.9.1 and 3.9.2) were kindly performed by Ruben Spohrer (AG Tenzer, FZI Core Facility for Mass Spectrometry, Mainz), MS measurements and data processing by Dr. Ute Distler (AG Tenzer, FZI Core Facility for Mass Spectrometry, Mainz).

3.9.1 In gel digestion

After SDS-PAGE and Coomassie staining, the protein lanes of interest were cut out of the gel and added to 200 μL 50 mM NH_4HCO_3 buffer in 50 % acetonitrile (ACN), followed by incubation in an ultrasonic bath for 5 min. The supernatant was discarded and the foregoing step was repeated. 200 μL 100 % ACN were added to the left gel pieces and again incubated in an ultrasonic bath for 5 min. The supernatant was discarded again and 100 μL 1 mM DTT solution were added to the gel pieces, followed by an incubation for 60 min at 56 °C. After cooling down the sample to RT, 100 μL iodoacetamide (IAA, c= 10 mg/mL) were applied and incubated for 45 min under light exclusion, followed by another addition of 100 μL 50 mM NH_4HCO_3 buffer in 50 % acetonitrile (ACN) and incubation in an ultrasonic bath for 5 min. After discarding the supernatant the last step was repeated. Afterwards, the gel pieces were incubated in 100 μL 100 % ACN in an ultrasonic bath for 5 min. The supernatant was discarded, the gel pieces heated at 56 °C for 1 min and then 25 μL trypsin solution (dilution 1:100) were added. Incubation was performed over night at 37 °C and the supernatant was added in an ice cooled tube

in which all following supernatants were collected. Now, the remaining gel pieces were incubated in 50 μL 50 % ACN solution with 1 % formic acid (FA) in an ultrasonic bath for 15 min. This step was performed twice, each time the supernatant was collected in the before mentioned tube. 100 μL 100 % ACN were then added to the gel sample and again incubated in an ultrasonic bath for 15 min. The supernatant was collected again and the gel pieces were discarded, followed by an incubation of the collected supernatants for 30 min at -80°C . The collected supernatants were then concentrated to a volume of 20 μL with a vacuum concentrator. and then centrifuged at 13 000 rpm for 15 min at 4°C . 15 μL of the supernatant were then added to 5 μL Enolase (100 fmol) and 5 μL 1 % FA. This mixture was then ready for mass spectrometric measurements.

3.9.2 In-solution digestion

To obtain samples for mass spectrometric measurements after the pulldown assay described in section 3.8, an in-solution digestion was performed. Proteins were precipitated with the "ProteoExtract™ Protein Precipitation Kit" (Merck Millipore, Darmstadt). 1 % RapiGest SF Surfactant solution were added ($\frac{1}{10}$ of sample volume) followed by an incubation for 15 min at 80°C . 8 mM DTT were added to the sample, incubated for 15 min at 56°C , followed by the addition of 15 mM IAA and an incubation at RT for 45 min. 1 μL trypsin and 8 mM DTT were added and incubated over night at 37°C . The pH of the sample was lowered to 3 with 1 M HCl an the sample incubated for 10 min at 37°C . After centrifugation for 30 min at 130 000 rpm and 4°C , 10 μL supernatant were mixed with 5 μL Enolase (100 fmol) and 10 μL 1 % FA to yield samples ready for MS measurements.

3.9.3 Liquid Chromatography Mass Spectrometry

After tryptic digestion (see subsections 3.9.1 and 3.9.2) the peptides were separated via nanoUPLC with a nanoAcquity UPLC system (Waters Corporation, Milford) on an Acquity UPLC HSS-T3 reverse phase column (high silica strength, $75\ \mu\text{m} \times 250\ \mu\text{m}$ 1.8 μm), which was equilibrated with Mobile Phase A (see table 2.2). In direct injection mode sample volumes between 0.7 μL and 0.6 μL were applied onto the reverse phase column, followed by a gradient flow of 5-40 % with Mobile Phase B over 90 min at a flow rate of 300 nL/min and a column temperature of

55 °C. Afterwards the column was washed with 90 % of Mobile Phase B and furthermore re-equilibrated.

A nano-ESI-Q-TOF mass spectrometer (Synapt G2-S HDMS, Waters Corporation) with an ion mobility separation (IMS) device was used for MS analysis performed in positive mode ESI. LC-MS data were collected in DIA mode using MS^E combined with IMS (HDMS^E) as well as in DDA mode using a top 10 method selecting the 10 most abundant ions for fragmentation.⁶³

3.9.4 Data Processing and Protein Identification

LC-MS DIA data were processed and searched with ProteinLynx Global SERVER (PLGS) (version 3.02 built 5 from Waters Corporation). DDA data were processed using the software package PEAKS (version 8, Bioinformatic Solution Inc., Waterloo, Canada). Protein identification was obtained searching a custom compiled database containing UniProtKB/SwissProt entries of the *E.coli* and human reference proteomes (entries: 4434 *E. coli*, 20 231 human) as well as the sequences of the N-terminal TRPV4 constructs. Sequence information for enolase (*Saccharomyces cerevisiae*) and common contaminants (e.g. human keratins, BSA, and trypsin) were added to the databases. Identified peptides had to match several search criteria:

1. Trypsin had to be the digestive enzyme.
2. Up to two missed cleavages were allowed.
3. Carbamidomethyl cysteine was defined as a fixed modification.
4. Methionine oxidation was defined as a variable modification.
5. Peptides had to have a minimum length of six amino acids.

The false discovery rate (FDR) for peptide and protein identification was assessed searching a reversed database. FDR was set to a 1 % threshold for database search in PLGS and PEAKS. HDMS^E collected data were post-processed with the in-house software ISOQuant in order to facilitate the data analysis.⁶³

3.10 Enzymatic assays

To validate the enzymatic activity of the recombinantly expressed and purified enzymes in the course of this work, enzymatic assays were performed as described below.

3.10.1 GTPase assay

Intrinsic GTPase activity of recombinantly expressed and purified human RhoA (see also subsection 3.7.5) was determined via the GTPase-Glo Assay (see also table 2.18) according to the manufacturers protocol. Luminescence was recorded with a FLUOStar Omega Microplate Reader (BMG Labtech). In this assay, GTPase activity is inversely correlated to the measured amount of luminescence.

3.10.2 ATPase assay

ATPase activity of recombinantly expressed and purified hsDDX3X (see also subsection 3.7.6) was determined via an cuvette-based *in vitro*-ATPase assay. The ATPase assay used in this work is based on the enzyme-linked regeneration of ADP to ATP coupled to the oxidation of NADH to NAD². The decrease of NADH and therefore the ATPase dependent hydrolysis of ATP can be determined with photometric measurements at 340 nm.⁸⁴ For this, the components of table 3.16 were mixed together in a cuvette with HEPES buffer (pH = 7). After 30 s 1 mM ATP was added to the mixture and due to the ATPase-dependent RNA-Helicase Activity of DDX3X, the mixture was supplemented with 1 μ M palindromic duplex RNA after 5 min (Sequence: 5'-UUUUUUUUUUUUUUUUUUUUUGGCGGCCGCC-3'). As a control, the well-characterized *B. subtilis* ATPase BmrA was also supplemented with hsV4 ARD to rule out unspecific effects on the lactate dehydrogenase and pyruvate kinase involved in this assay. Measurements were carried out at RT with a Perkin-Elmer Lambda 25 Photometer.

Table 3.16: Sample composition for the *in vitro*-ATPase assay

Component	
MgCl ₂	1 μ M
Ascorbinic acid	1 μ M

Component	
Phosphoenolpyruvate	3 μ M
Pyruvate kinase	0.05-0.08 units/ μ L
Lactate dehydrogenase	0.08-0.12 units/ μ L
hsDDX3X	3 μ M
BmrA	3 μ M
hsV4N construct	12 μ M
duplex RNA	1 μ M
ATP	1 μ M

3.10.3 Ubiquitylation assay

To determine the E3 Ubiquitin ligase activity of recombinantly expressed and purified human ITCH (see also subsection 3.7.7) an *in vitro*-ubiquitylation assay was performed. For this, the components of table 3.17 were incubated at 30 °C for up to 3 h in 10 mM Tris (pH=7.4) with 5 mM MgCl₂. Out of this mixture, samples were taken after several time points for subsequent SDS-PAGE and Coomassie staining.

Table 3.17: Sample composition for the *in vitro*-Ubiquitylation assay

Component	Concentration [μ M]
ATP	5000
Ubiquitin	100
E1 Ubiquitin ligase UBE1	2
E2 Ubiquitin ligase Ubc5Hc	1
E3 Ubiquitin ligase ITCH	10
hsV4N construct	20

3.11 Blue Native-PAGE (BN-PAGE)

BN-PAGE is a straight-forward way to identify direct protein-protein interactions, especially for proteins which isoelectrical points are > 8 , as these proteins do not migrate in a PAGE under Laemmli-conditions.⁸⁵ Here, Coomassie G-250 is added into the discontinuous PAGE to create a net negative charge to allow protein migration towards the anode. In this work, BN-PAGE was used to determine the minimal binding side of ITCH at hsV4N. For this, 10 μ M ITCH and 20 μ M of the respective hsV4N construct were mixed in a tube with 10 mM Tris (pH=7.4) supplemented with 5 mM $MgCl_2$ as reaction buffer. The protein mixture was incubated at 30 °C for 1 h. After this, the protein mixture was supplemented with Coomassie G-250 to an end concentration 0.25 % (w/v). The PAGE were run with 4 - 15 % Mini-Protean[®] TGX[™] Precast Protein Gels with a electrophoresis cathode buffer (see table 2.2) for 3 h at 4 °C. After this, Coomassie staining was performed and relevant bands were cut out to provide them for mass spectrometric verification (Mass Spectrometry Core Facility, Johns Hopkins School of Medicine, Baltimore, USA).

3.12 Circular dichroism (CD) spectroscopy

Circular dichroism (CD) measurements were performed on a Jasco-815 CD spectrometer with a spectral range between 195 and 260 nm at 20 °C. The scanning intervals were set to 1 nm, the scanning speed to 50 nm/min and the band-width to 5 nm. CD data are often reported as a mean residue ellipticity $[\Theta]_{mrw,\lambda}$ (deg cm^2 $dmol^{-1}$). The conversion from the measured ellipticity Θ (deg) to the mean residue ellipticity $[\Theta]_{mrw,\lambda}$ is described by equation 3.1.

$$[\Theta]_{mrw,\lambda} = \frac{MRW \cdot [\Theta]}{10 \cdot c \cdot d} \quad (3.1)$$

Mean residue weight (MRW) is calculated with $MRW = \frac{M}{N-1}$, where M is the molecular weight in Dalton and N is the amino acid number of the measured protein. The secondary structure content was predicted with analyzing the CD spectra with the CAPITO tool (<https://capito.uni-jena.de>). The Chou-Fassmann algorithm predicts secondary structures based on empiric data in which amino acids show preferences for distinct secondary structures. Furthermore,

CAPITO compares the measured spectra with basis spectra data sets. A nearest-neighbor approach determines the 25 best matching references curves defined by closest proximity. At last, the lowest area differences are compared to reference curves.

3.13 NMR spectroscopy

To obtain uniformly ^{15}N -labeled proteins for ^{15}N -HSQC spectra, *E. coli* BL21 Gold cells were transfected and the proteins expressed as described in sections 3.1.1 and 3.7, however, the cells were grown in M9 medium (see table 2.2) to ensure that $^{15}\text{NH}_4\text{Cl}$ is the only nitrogen source for protein expression. NMR spectra of respective proteins were recorded at 25 °C on Bruker AVANCE 600, 700 and 800 MHz spectrometers equipped with cryogenic triple resonance probes (Bruker, Karlsruhe) at the Centre for Biomolecular Magnetic Resonance (BMRZ) (Goethe-University, Frankfurt a.M.). $^1\text{H},^{15}\text{N}$ -HSQC spectra were measured using standard pulse sequences and processed using TOPSPIN 3.5 (Bruker, Karlsruhe).⁸⁶

3.14 Cross-linking mass spectrometry (XL-MS)

XL-MS is a powerful tool for investigations of protein-protein interactions (PPIs) and the interfaces of these interaction. Due to the chemical cross-linking between functional groups of amino acid side chains XL-MS is advantageous to capture and identify weak or transient PPIs. Here, H12/D12-disuccinimidyl suberate (H12/D12-DSS) was used, cross-linking between the amide groups of lysines. Purified (hsV4N and DDX3X as well as hsV4N and ITCH) proteins were mixed in a molar ratio of 1:1 to a final concentration of 1 mg/mL in 100 μL . H12/D12-DSS was freshly dissolved in DMF prior use and added to the protein mixture at a final concentration of 1.5 mM. The cross-linking reaction was incubated for 2 h on ice and quenched with the addition of ammonium bicarbonate at a final concentration of 500 mM. The mixture was further incubated on ice for additional 2 h. Samples were flash-frozen in liquid nitrogen and stored at -20 °C until further use. Sample processing, MS measurements and analysis were kindly carried out by M. Sc. Jasmin Jansen (Working group Stengel, University of Konstanz).⁸⁷

4 Results

4.1 A beginning to elucidate the versatile TRPV4 N-terminal protein interactome - the tip of the iceberg

4.1.1 Purification of biotinylated TRPV4 N-terminal proteins

The protein interactome of a cell is not a static structure of probable binary protein-protein interactions (PPIs). It is a reflection of the cells state and therefore indicates protein abundance, post-translational modifications, cell cycle phase or the stress level of a cell. Due to this broad variety of possible conditions, the protein interactome of a cell is very dynamic and specific biochemical methods can only yield snapshots of protein interactions in certain biological situations. To obtain a comprehensive view of the protein interactome, shotgun mass spectrometry is the method of choice.^{73,88} This work focuses on the protein interactome of the full-length TRPV4 N-terminus (here referred to as hsV4N), as this portion of the full-length ion channel is a notorious hot-spot for disease-causing point mutations.^{27,56,89,90} Furthermore, hsV4N plays an integral role in channel sensitization as well as desensitization and harbors a number of pivotal protein, lipid and small molecule interaction sites, like a phosphoinositide binding domain (PBD) and a proline rich region (PRR), which are followed by six α -helical ankyrin repeats, the ankyrin repeat domain (ARD).^{22,39} Previously, a protocol was established to obtain the hsV4N protein interactome after pulldown assays in HEK293 cell lysates followed by shotgun proteomics performed in cooperation with Dr. [REDACTED] (RG [REDACTED] University Medicine Mainz, JGU Mainz).⁷⁶ This protocol required recombinant expression, *in vivo* biotinylation as well as protein integrity investigations of several TRPV4 N-terminal constructs with an so-called avidin-tag (here referred as Avi). This tag allows side-specific *in vivo* biotinylation of a lysine in the avidin-tag itself (single letter code avidin-tag: GLNDIFEAQKIEWHE).⁹¹ In addition to

the already used and validated full-length hsV4N with avidin-tag (hsV4N wt Avi), before mentioned protocol was optimized for the TRPV4 ankyrin repeat domain (here referred as hsV4 ARD), including the selected disease-causing mutations R232C and K276E (figure 4.1). The TRPV4 R232C mutation leads to Charcot-Marie-Tooth Type 2C (CMT2C)⁵⁴, whereas TRPV4 K276E results in fetal akinesia - a combined phenotype of metatropic dysplasia with putative neurodegenerative symptoms.⁹² Protein expression, *in vivo* biotinylation and purifications were performed as described in subsection 3.7.4. All size exclusion chromatograms (SEC) of used TRPV4 N-terminal constructs in figure 4.1 show narrow gaussian peaks with expected elution volumes for all biotinylated proteins (see section 6.2 for SEC purification of unbiotinylated proteins). Coomassie stained SDS-PAGEs show pure proteins and a Streptavidin-Peroxidase (Strep-POD) dot-blot confirms successful biotinylation. However, hsV4N wt Avi shows a significant stronger signal in the Strep-POD dot blot than the hsV4 ARD Avi constructs. Image analysis of the Strep-POD dot blots with Fiji shows a 90 % weaker biotinylation efficacy of the hsV4 ARD Avi constructs compared to hsV4N Avi (data not shown). Adjustment of the used hsV4 ARD Avi concentrations was sufficient enough for successful pulldowns due to the strong interaction between biotin and streptavidin with a K_D in the femtomolar range.^{91,94-96} CD spectra show, as also previously reported²², that hsV4N consists of a large α -helical part, which is contributed by the ARD (aa 149 - aa 398), and a large unstructured region (aa 1-aa 149). Comparison of the CD spectra between biotinylated and non-biotinylated hsV4 ARD Avi constructs shows no change in the α -helical structure, which is also underlined by secondary structure prediction via CAPITO⁹³. Only biotinylated hsV4N wt Avi supposedly harbors a marginal β -sheet

Figure 4.1 (*facing page*): **Purification of *in vivo* biotinylated and structural intact TRPV4 N-terminal constructs.** **A** Schematic topology model of TRPV4 N-terminal constructs used for protein interactome investigations via pulldown assays and subsequent mass spectrometry in this work. HsV4N represents the full-length human TRPV4 N-terminus with important interaction sites like the phosphoinositide binding site (PBD), proline rich region (PRR) and the ankyrin repeat domain (ARD). Avi = avidin tag (single letter code: GLNDIFEAQKIEWHE). His₆ = hexa-histidine tag (single letter code: HHHHHH). **B** SEC purifications of biotinylated hsV4N wt Avi and hsV4 ARD Avi constructs. SEC runs were either performed with a HiLoad Superdex 200 pg or a HiLoad Superdex 75 pg preparative SEC column. Inlets show Coomassie stained 15 % SDS-PAGEs of collected and concentrated fractions after SEC, furthermore a Strep-POD dot blot indicating biotinylated proteins of the respective proteins. x-axis: eluted volume in mL, y-axis: absorbance at 280 nm, M = marker in kilodalton (kDa). **C** Comparison of far UV CD spectra of purified biotinylated and non-biotinylated hsV4N constructs. Spectra were measured at 293 K and proteins were used at 2 μ M concentration in SEC buffer with a final concentration of 30 mM NaCl. Inlets show secondary structure prediction performed with CAPITO.⁹³ The predicted α -helix/ β -sheet/random coil content of the purified proteins is for non-biotinylated hsV4N wt Avi 53%/0%/46 %, hsV4 ARD wt Avi 76%/0%/24 %, hsV4 ARD R232C Avi 74%/0%/26 % and hsV4 K276E Avi 76%/0%/24 %. Biotinylated proteins show the following secondary structure content distribution: hsV4N wt Avi 40%/14%/46 %, hsV4 ARD wt Avi 76%/0%/24 %, hsV4 ARD R232C Avi 74%/0%/26 % and hsV4 ARD K276E Avi 76%/0%/24 %. x-axis: mean residue ellipticity ($[\Theta]_{m,w,\lambda}$) in 10^{-3} deg cm² dmol⁻¹, y-axis: wavelength λ in nm.

fold content compared to non-biotinylated hsV4N wt Avi.

4.1.2 The TRPV4 N-terminal protein interactome in HEK293 cells derived via mass spectrometry

For the elucidation of the TRPV4 N-terminal protein interactome, biotinylated and non-biotinylated constructs (see subsection 4.1.1) were subjected to streptavidin-dependent pulldowns with HEK293 cytosolic extracts. Table 4.1 lists all samples which were used in the pulldowns with HEK293 cytosolic protein extracts (see figure 4.2 for workflow and section 3.8 for protocol). Shortly, streptavidin-coated magnetic beads were incubated with the respective purified TRPV4 N-terminal construct (biotinylated or non-biotinylated), washed and then incubated with the cytosolic extract of HEK293 cells. Additionally, samples with biotinylated constructs were supplemented with 2 mM Ca^{2+} during the HEK293 cytosolic extract incubation step to mimic an increased intracellular Ca^{2+} concentration as it would be observed upon TRPV4 ion channel activation.

Table 4.1: Sample overview of hsV4N interactome pulldowns with HEK293 cytosolic protein extracts

Construct	Biotinylated	Sample supplement
hsV4N wt Avi	Yes	none
hsV4 ARD wt Avi	Yes	none
hsV4 ARD R232C Avi	Yes	none
hsV4 ARD K276E Avi	Yes	none
hsV4N wt Avi	Yes	2 mM Ca^{2+}
hsV4 ARD wt Avi	Yes	2 mM Ca^{2+}
hsV4 ARD R232C Avi	Yes	2 mM Ca^{2+}
hsV4 ARD K276E Avi	Yes	2 mM Ca^{2+}
<i>Controls</i>		
hsV4N wt Avi	No	none
hsV4 ARD wt Avi	No	none
hsV4 ARD R232C Avi	No	none
hsV4 ARD K276E Avi	No	none

Figure 4.2: **Outline of the proteomics workflow performed in this work.** See sections 3.8 and 3.9 for protocols. **A** To enrich cytosolic proteins, plasma membranes of HEK293 cells were permeabilized with digitonin. This detergent releases cytosolic proteins into the supernatant while contaminations by other cell compartments are reduced to a minimum.⁸³ **B** Schematic layout of the hsV4N interactome pulldown. Streptavidin-bound magnetic beads were loaded with respective purified hsV4N Avi construct (see also figure 4.1). Loaded beads were incubated in HEK293 protein extract containing cytosolic proteins. As a control, beads were also incubated with non-biotinylated TRPV4 N-terminal constructs to rule out unspecific interactors (background). **C** After elution, putative interactors were trypsin digested to peptides. These peptides were then separated by ultra high-performance liquid chromatography (UPLC) and directly supplied into the mass spectrometer via electron spray ionization (ESI). MS data were collected in data independent acquisition (DIA) mode. All steps in C were performed in cooperation with [redacted] University Medicine Mainz).^{63,72,73}

The HEK293 protein interactome of the TRPV4 full-length N-terminus

Figure 4.3 shows the volcano plots of two independent ultra high-definition mass spectrometry^E (UDMS^E) measurements of hsV4N wt Avi. In these volcano plots, only significantly detected proteins are shown. All samples listed in table 4.1 were measured in technical quadruplicates. Proteins were considered as significant, if the p -value was ≤ 0.05 (Benjamini-Hochberg corrected Student's t -test) and the \log_2 fold change for respective protein between biotinylated hsV4N wt Avi and non-biotinylated hsV4N Avi wt control sample was ≥ 1 . Additionally, only proteins which appeared in both independent UDMS^E measurements were considered as highly probable hsV4N wt Avi protein interactome members. Significant proteins showed different fold changes between the two independent measurements (black and grey dots in figure 4.3), indicating a high sensitivity of the UDMS^E measurements towards different NaCl concentrations

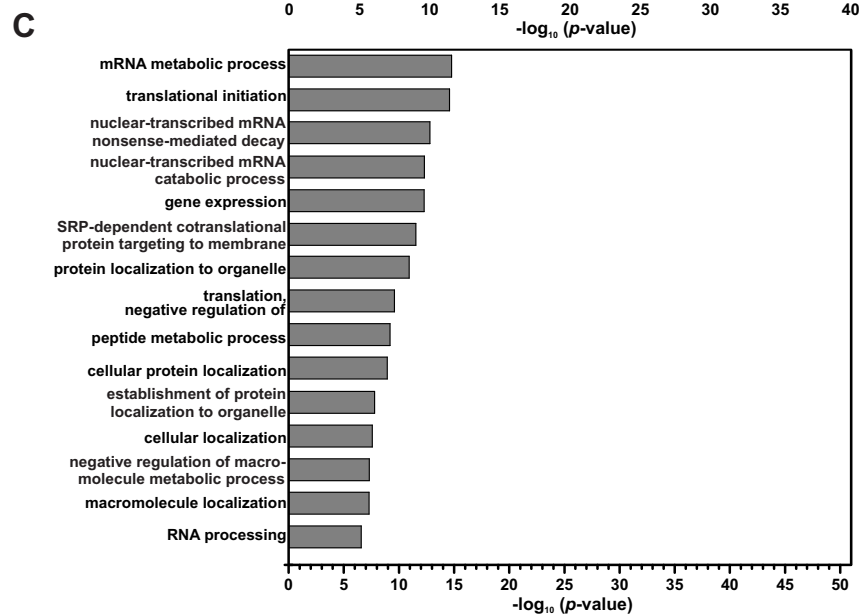

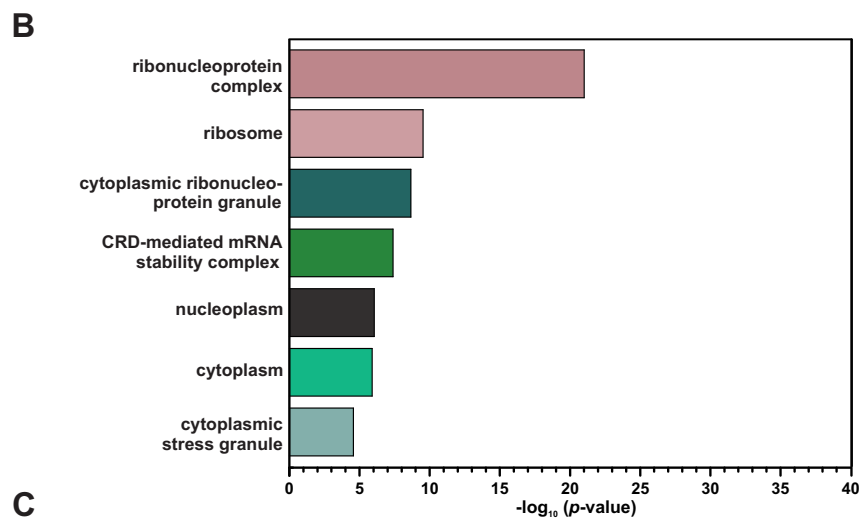

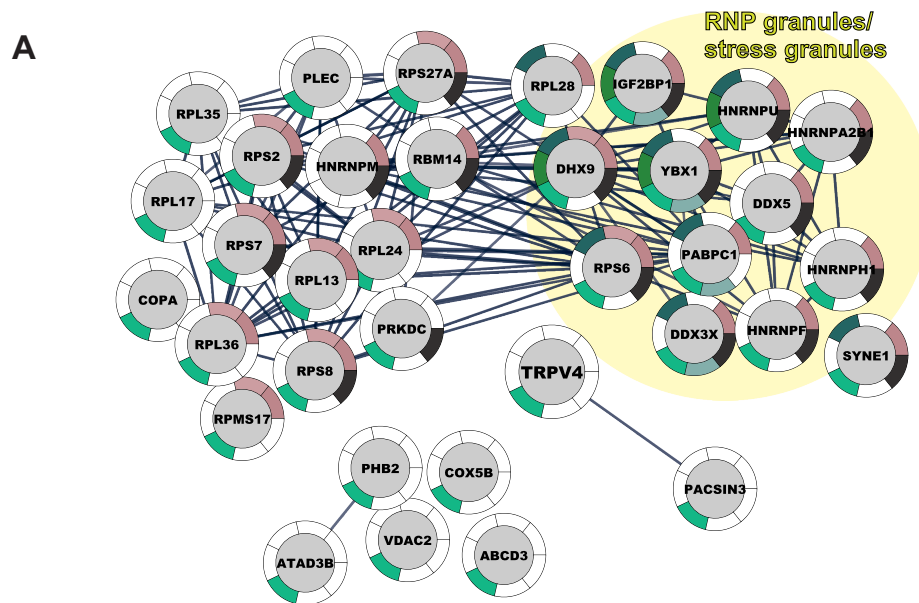

Figure 4.3: **UDMS^E measurements revealed up to 64 probable hsV4N protein interactors.** **A** Volcano plot of two independent HEK293 protein interactome UDMS^E measurements from hsV4N wt Avi. 34 proteins were considered as significant. **B** Volcano plot of two independent HEK293 protein interactome UDMS^E measurements from hsV4N wt Avi with 2 mM Ca²⁺ sample supplementation. 64 proteins were considered as significant. Black (hsV4N wt Avi, 300 mM NaCl buffer) and dark gray points (hsV4N wt Avi, 750 mM NaCl buffer) indicate significant, detected HEK293 protein interactome candidates in both independent experiments. Each pulldown was measured in quadruplicates. Horizontal light gray lines indicate the p -value = 0.05 (Benjamini-Hochberg corrected Student's t -test) of the quadruplicates of each UDMS^E measurement. Vertical light gray lines indicate a \log_2 fold change ≥ 1 . For a full list of hsV4N interactors, see tables 6.3 and 6.4

supplemented in the hsV4N wt Avi SEC buffer. Data analysis resulted in 34 relevant hsV4N wt Avi interaction partners in samples without Ca²⁺ supplementation and 64 hsV4N wt Avi interaction partners in the samples with Ca²⁺ supplementation (see figures 4.4 A and 4.5 A), including the known direct TRPV4 interactor PACSIN3 in both conditions.^{22,23,70,71} Gene Ontology enrichment analysis (GO enrichment analysis) is a technique to interpret high-throughput data in terms of over- or underrepresentation of certain genes in respective experiment. The Gene Ontology classification assigns genes to sets of predefined bins depending on their role in cellular processes or functional characteristics.⁹⁷ GO enrichment analysis with STRING⁹⁸ via Cytoscape 3.8.0 demonstrated that all detected proteins are associated with the cytoplasm, which is composed out of the cytosol and cytoskeleton, indicating successful extraction of mainly cytosolic proteins. Only HNRNPM_HUMAN represents an exception, as it is associated with the nucleoplasm but also with ribonucleoprotein complexes - like the majority of the cytosolic proteins in the here disclosed network. Like HNRNPM_HUMAN, a small portion of other proteins could also be associated with the nucleoplasm, but are known for their nucleocytoplasmic shuttling.⁹⁹ Additionally, GO enrichment analysis and manual data curation connected a considerable amount of detected proteins with cytoplasmic ribonucleoprotein or cytoplasmic stress granules (13 proteins, see figure 4.4 and table 6.3). *Cytoplasmic ribonucleoprotein granule* is a collective GO term for distinct RNA-binding protein-containing foci in the cytoplasm, including amongst others neuronal transport granules, P-bodies and stress granules. Stress granules, appearing as their name says after various stress factors like oxidative or hyperosmotic stress in the cytosol, form

via liquid-liquid phase separation of pre-existing RNA-binding protein (RBP) complexes.^{100,101} The exact role of stress granules in neuronal (patho)physiological processes remains largely unknown. It is known that stress granule formation is accompanied by polysome disassembly and translational arrest.^{102–105} Stress granules are mostly composed out of translation initiators, RBPs, 40S ribosomes and polyadenylated mRNAs and therefore are proposed to play a protective role in cells by promptly providing the undamaged translation machinery for important household proteins after their disassembly due to stress withdrawal.^{106–110} Stress granules and other cytoplasmic ribonucleoprotein granules show major overlaps in their proteome but are also known for their highly variable and dynamic protein compositions, transitioning from one granule to the other in dependency of the cellular stress level.^{101,107–109,111–114} Liu-Yesucevitz *et al.* showed that potassium chloride (KCl)-induced depolarization in primary neurons, leading to dramatically elevated cytoplasmic Ca^{2+} levels, induces a transformation of neuronal mRNA transport granules to stress granules.¹¹⁵ Interestingly, it was shown that neuropathy-causing mutations of TRPV4 show an elevated baseline Ca^{2+} -influx activity of the channel, also leading to higher cytosolic Ca^{2+} -concentrations.^{53,54} In the present work, upon Ca^{2+} -supplementation, the amount of ribosomal proteins in the hsV4N interactome considerably increased, but also the number of proteins associated with cytosolic ribonucleoprotein granules (20 proteins, figure 4.5 and table 6.4). In both conditions, without and with Ca^{2+} , known stress granule formation proteins are present, namely YBX1, IGF2BP1, PAPBC1 and DDX3X.^{107,108,116–120} Furthermore, upon Ca^{2+} supplementation proteins associated with the GO term *supramolecular fiber* were detected. Supramolecular fibers are defined as protein complexes which form fiber-shaped structures, like microtubule or actin filaments. Fiber-like structures were shown to spur the maturation of phase-separated droplets to more stable and less dynamic structures and therefore impair an important property of stress granules: the fast disassembly within minutes after stress removal.^{101,102,117,121–130} Amyotrophic lateral sclerosis (ALS)-causing mutations in stress granule proteins, especially in the intrinsically disordered regions (IDRs) of RBPs, were shown *in cellulo* to lead to insoluble inclusions. This is particularly interesting, as the TRPV4-associated neuropathy Charcot-Marie-Tooth Type 2C is also referred as a so-called "ALS-mimic", due to the shared clinical symptoms.¹³¹ Furthermore, insoluble inclusion formations were also observed

Figure 4.4 (*facing page*): **The hsV4N protein interactome determined via UDMS^E.** **A** STRING interaction network of detected, significant hsV4N interactome proteins. Outer ring color of nodes represent Gene Ontology (GO) terms for cell components, also shown in B. For a full list of protein interactors see table 6.3 **B** Selected GO terms for cell components of significant, detected hsV4N interactome proteins via UDMS^E after GO enrichment analysis. **C** Selected GO terms for cell processes of significantly detected hsV4N interactome proteins via UDMS^E after GO enrichment analysis (Benjamini-Hochberg corrected, $p < 0.05$)

with wild-typic RBPs after induction of repeated cycles of stress granule assembly and disassembly in short time, mimicking chronic stress conditions.^{100,132} Permanent Ca^{2+} influx, for example via neuropathy-causing mutations in TRPV4, could thus lead to a pathological switch from dynamic granules to aggregates, which then impair the important roles of ribonucleoprotein granule functions like dendritic and axonal mRNA transport and local translation. Due to the unique cellular structure of neurons, this cell type is more sensitive to the lacking clearance of these aggregates and therefore explain the high neurotoxicity of these inclusions.^{133–135} Thus, TRPV4 and its disease-causing mutations provide multiple factors to be a part of the stress granule machinery. Neuropathy causing TRPV4 mutations, like TRPV4 R232C, lead to chronic stress levels due to increased Ca^{2+} -influx activity. Based on the data shown here, hsV4N itself could act as a direct interaction site for stress granule key proteins and in combination with the Ca^{2+} -dependent recruitment of proteins involved in supramolecular fiber formation, possibly leading to neurotoxic aggregates.

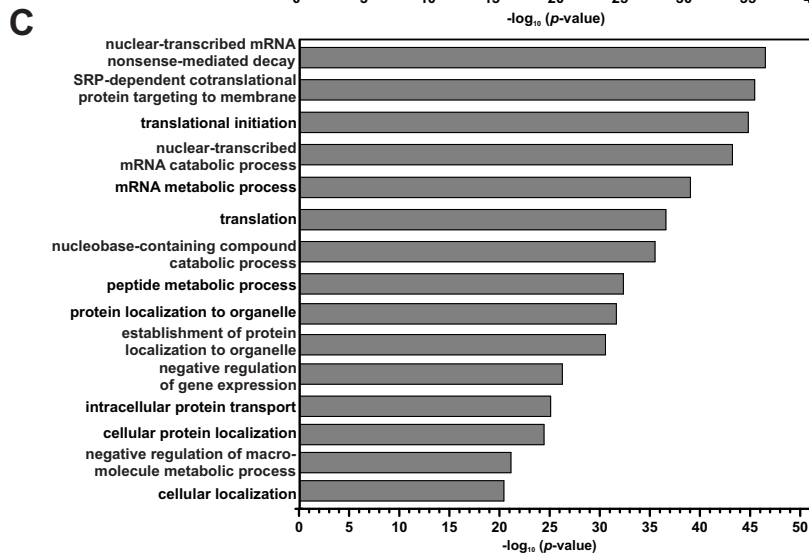

To narrow down the interaction sites of the previously identified hsV4N interactors, several hsV4 ARD constructs were probed in the same UDMS^E experimental set-ups as hsV4N. The ARD of TRPV4 is a hot-spot for disease-causing mutations.^{27,56} Here, besides the wild-typic hsV4 ARD, hsV4 ARD harboring the neuropathy-causing R232C mutation as well as the fetal-akinesia causing hsV4 ARD K276E mutation were investigated with regard to their HEK293 cells protein interactome. Figures 4.6 A-F show the STRING interaction map and GO enrichment analysis of the respective hsV4 ARD construct without and with Ca^{2+} -supplementation. To provide a better overview, only proteins associated with ribonucleoprotein granules and/or stress granules via GO analysis and/or manual data curation are shown in the interaction maps (figures 4.6 A-E). Upon Ca^{2+} -supplementation, the amount of RBPs increases in the case of hsV4 ARD wt (figures 4.6 A and B) and R232C (figures 4.6 C and D). Only for hsV4 ARD K276E the amount of ribonucleoprotein granule associated proteins decreases upon Ca^{2+} -supplementation (figure 4.6 E and F). It should be noted that TRPV4 R232C showed elevated basal Ca^{2+} -influx level *in cellulo*.^{53,54} Basal Ca^{2+} -influx activities of TRPV4 K276E were not evaluated until now, but due to the severe clinical outcome of this mutation it could be assumed that this mutation also leads to a gain-of-function phenotype of the channel.⁴⁸ It is therefore possible that the interactions after Ca^{2+} supplementation are more representative for the possible aberrant PPIs in the presence of disease-causing mutations (figures 4.6 C and D (hsV4 ARD R232C) as well as E and F (hsV4 ARD K276E), respectively).

Comparing the interactome composition between the different TRPV4 N-terminal constructs, it seems that the interactome is highly variable - not only between the samples without and with

Ca²⁺-supplementation, but also between hsV4 ARD wt and mutated hsV4 ARDs, as well as between hsV4N and hsV4 ARD wt (see figure 4.7). These variations could thus hint towards an important regulatory role of the intrinsically disordered region (hsV4 IDR), preceding hsV4 ARD in hsV4N, on the protein interactions of hsV4 ARD. Interestingly, throughout all UDMS^E measurements, the ATP-dependent RNA-helicase DDX3X was detected as a part of the hsV4N protein interactome, more precisely of hsV4 ARD protein interactome. DDX3X was shown to directly interact with full-length TRPV4 via a yeast-two hybrid screening (Y2H), although the species of used TRPV4 was not mentioned in the publication.¹³⁶ Due to the central role of DDX3X in stress granule formation and its role in neurodegeneration, section 4.2 gives a closer look on the probable direct interaction between DDX3X and hsV4N.^{119,137–139}

The TRIP database (<http://trpchannel.org/>) is a manually curated database of PPIs for mammalian TRP channels and therefore gives an overview of known PPIs of TRPV4.^{16,29,30} Most of the listed interactors in the TRIP database were determined via co-immunoprecipitations (co-IPs), co-immunofluorescence staining and/or FRET measurements with endogenous proteins and/or overexpressing HEK293 cells (see also table 6.1). The TRPV4 interacting protein classes which are represented in the TRIP database are very diverse, including amongst others, transmembrane proteins (TRPC1, AT1aR, AQP4 e.g.), kinases (FYN, LYN e.g.), E3 ubiquitin ligases (ITCH) and cytoskeletal proteins (α -actin and α -tubulins). Another reliable database for PPIs is BioGrid (<https://thebiogrid.org/>). BioGrid lists the same protein interactors as the TRIP database for human TRPV4.¹⁴⁰ In both databases, no RBPs or other proteins involved in cytoplasmic ribonucleoprotein granules are indicated. One reason for this could be that most of the PPI determinations were conducted via co-IPs of full-length TRPV4 and subsequent western blotting with immunostaining, only allowing to investigate pin-pointed PPIs with certain proteins. Comprehensive mass spectrometric proteomics analysis of isolated TRPV4 domains like the here used hsV4N as a bait were not published until now. Donate-Macian *et al.* used full-length TRPV4 as a bait for Y2H screening of direct TRPV4 interactors, the species of the used TRPV4 construct was not mentioned though, as pointed out above. Besides DDX3X, UBAP2L was also shown to directly interact with TRPV4.¹³⁶ In this thesis, UBAP2L was detected in UDMS^E

Figure 4.5 (*facing page*): **The hsV4N wt Avi protein interactome determined via UDMS^E with Ca²⁺ sample supplementation.** **A** STRING interaction network of detected, significant hsV4N interactome proteins. Outer ring color of nodes represent Gene Ontology (GO) terms for cell components, also shown in B. For a full list of protein interactors see table 6.4 **B** Selected GO terms for cell components of significant, detected hsV4N wt Avi interactome proteins via UDMS^E after GO enrichment analysis. **C** Selected GO terms for cell processes of significant, detected hsV4N interactome proteins via UDMS^E after GO enrichment analysis.

experiments conducted with hsV4 ARD wt (figures 4.6 A and B). However, the protein overlap between UDMS^E and Y2H is low, which was also already shown after comparison of other affinity purification MS (AP-MS) experiments with Y2H screens with the same bait protein. This emphasizes the highly complementary nature of both techniques: while MS approaches provide large-scale data on protein complexes, with additional Y2H results it is possible to break these complexes down into binary PPIs.¹⁴¹

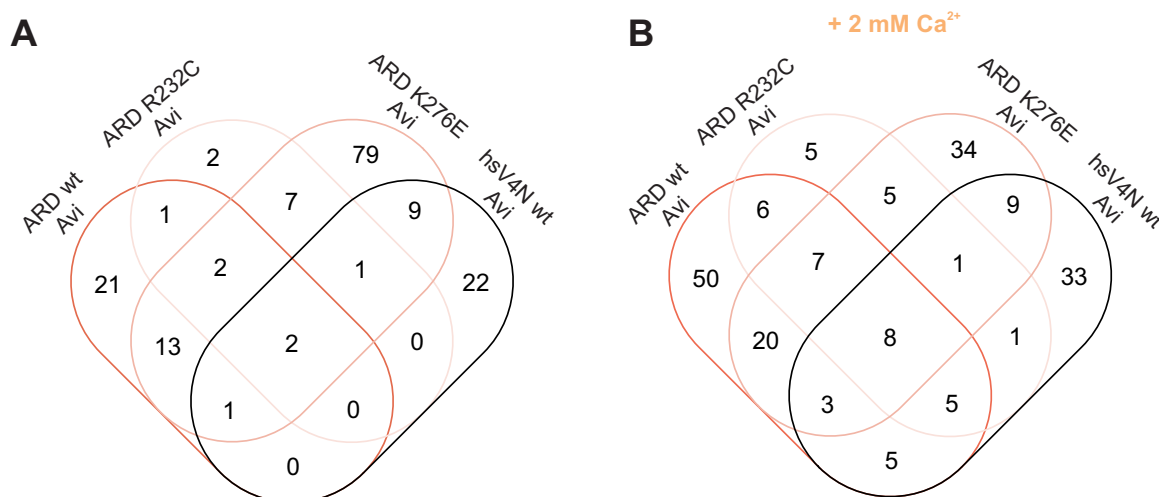

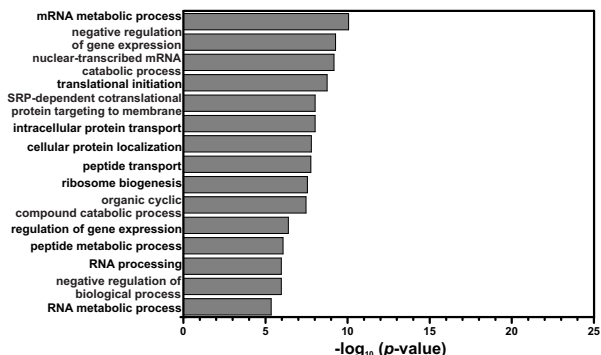

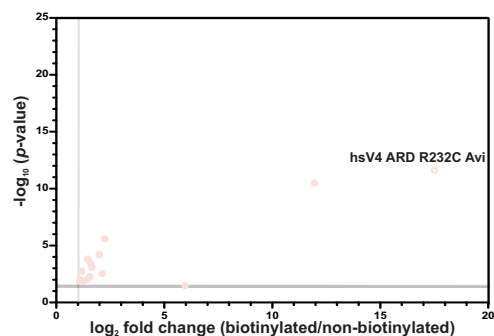

Figure 4.7: Venn diagrams of overlapping proteins detected in respective UDMS^E experiments without (A) and with Ca²⁺ sample supplementation (B). For full lists of detected proteins see tables 6.3, 6.4, 6.5, 6.6, 6.7, 6.8, 6.9 and 6.10

Chapter 4. Results

The UDMS^E interactome results shown in this thesis revealed ribonucleotide binding proteins as a new potential class of TRPV4 interacting proteins and thus indicate TRPV4 as a until now unknown player in the regulatory mechanism of cytoplasmic ribonucleoprotein granule formation via its cytosolic N-terminus. The following sections take a closer look on chosen TRPV4 PPIs *in vitro* and *in cellulo*.

4.2 Birds of a feather flock together - the interaction between the two protean proteins TRPV4 and DDX3X

As described in sub chapter 4.1, elaborate mass spectrometry (MS)-based interactome studies of hsV4N showed a significant amount of RNA-binding proteins (RBPs) as a new class of potential TRPV4 binding partners. The composition of detected RBPs varied between different conditions, like the presence of disease-causing mutations and/or Ca^{2+} -supplementation. Intriguingly, the ATP-dependent RNA-helicase DDX3X was consistently detected in all samples. Recently, Donate-Macian *et al.*¹³⁶ showed via a Y2H screening that DDX3X is a direct interactor of full-length TRPV4. The MS-based interactome studies conducted in this work indicate that DDX3X possibly binds to the TRPV4 N-terminus with the ARD (hsV4 ARD) as a minimal binding site. Log_2 ratios of DDX3X in respective MS-measurements already suggested elevated DDX3X binding-levels with mutation-bearing hsV4 ARDs (hsV4 ARD R232C and K276E, respectively) in comparison to hsV4 ARD wt or hsV4N (see tables 6.3, 6.4, 6.5, 6.6, 6.7, 6.8, 6.9 and 6.10). To conduct *in vitro* experiments regarding the probable direct interaction between DDX3X and hsV4 ARD, recombinant DDX3X and TRPV4 N-terminal constructs were purified and their structural integrity confirmed as shown in figure 4.8 (see subsections 3.7.1 and 3.7.6 for purification protocols). hsV4 ARD K276E showed heavy precipitation behavior in all subsequent *in vitro* studies and is therefore not shown in following procedures and experiments.

Figure 4.8 (*facing page*): **Purification of recombinant human TRPV4 N-terminal constructs and human DDX3X.** **A** Topology model of recombinantly expressed human TRPV4 N-terminal constructs and human DDX3X. The DDX3X construct was optimized for future nuclear magnetic resonance spectroscopy experiments, comprising supposedly unstructured regions which include residues aa 1 - 120 and aa 582 - 662. His₆ = hexa-histidine tag (single letter code: HHHHHH), TEV = Tobacco Etch Virus Cleavage Site (single letter code: ENLYFQG), DEAD = DEAD domain (RecA-like domain 1), HELICc = C-terminal helicase domain (RecA-like domain 2). See figure 4.14 A for full-length DDX3X. His₆-tags with preceding or subsequent TEV Cleavage Site were removed. **B** SEC purifications of human TRPV4 N-terminal constructs and human DDX3X. SEC runs were performed with either a HiLoad Superdex 200 or a HiLoad Superdex 75 pg preparative SEC column. Inlets show Coomassie stained 15 % SDS-PAGES of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbance at 280 nm, M = marker. **C** Comparison of far UV CD spectra of purified human TRPV4 N-terminal constructs and human DDX3X, respectively. Spectra were measured at 293 K and proteins were used at 1 μM concentration in either SEC Buffer with a final NaCl concentration of 30 mM (TRPV4 N-terminal constructs) or DDX3X SEC buffer with a final concentration of 12.5 mM NaCl (DDX3X). Inlets show secondary structure prediction performed with CAPITO.⁹³ The predicted α -helix/ β -sheet/random coil content of the purified proteins is for hsV4N 53%/0%/47%, hsV4N R232C 33%/13%/53%, hsV4 ARD wt 68%/0%/32%, hsV4 ARD R232C 78%/0%/32% and DDX3X 40%/14%/46%. y-axis: mean residue ellipticity ($[\Theta]_{\text{mrw},\lambda}$) in 10^{-3} deg cm^2 dmol^{-1} , x-axis: wavelength λ in nm.

Figure 4.9: **hsV4 ARD, but not hsV4N, decreases the DDX3X ATPase activity.** **A** In an enzyme-coupled ATPase assay, DDX3X showed a time-dependent duplex RNA (dxRNA)-stimulated ATPase activity (black) and a negligible ATPase activity in the absence of dxRNA (DDX3X w/o dxRNA, dark gray), in agreement with the literature.^{84,142} **B** DDX3X ATPase activity in the presence of several TRPV4 N-terminal constructs. Error bars indicate SDs of determined slopes after natural logarithmic conversion and linear regression. **C+D** DDX3X showed decreased ATPase activity in the presence of hsV4 ARD. Interestingly, hsV4N itself and the ARD preceding intrinsically disordered region (IDR) consisting of amino acids 1-149 of hsV4N do not demonstrate such an effect on DDX3X. DDX3X was used at a concentration of 3 μM and TRPV4 N-terminal constructs at 12 μM , resulting in a 1:4 ratio. After 30 s samples were supplemented with ATP and after 5 min with duplex RNA (dxRNA), both at a final concentration of 1 μM . ATPase activity was determined by an ATP-dependent enzyme-coupled oxidation from NADH to NAD⁺, resulting in a time-dependent absorption decrease at 340 nm. Measurements were normalized to DDX3X ATPase activity. Error bars indicate SDs of three measurements of three independent DDX3X purifications for each condition. Used TRPV4 N-terminal constructs originated from one purification. x-axis = time in s, y-axis = extinction at 340 nm in arbitrary units. IDR was kindly provided and fully characterized by Dr. [redacted] and [redacted].¹⁴³

To ensure enzymatic activity of purified DDX3X, an enzyme-coupled ATPase assay was performed (see figures 4.13 C and D). In agreement with Epling *et al.*¹⁴², DDX3X showed a time-dependent duplex RNA (dxRNA)-stimulated ATPase activity and a negligible ATPase activity in the absence of dxRNA (figure 4.9 A). When supplemented with hsV4 ARD, the ATPase activity of DDX3X significantly decreased, whereas no effect was observed upon hsV4N supplementation (see figure 4.9). Interestingly, DDX3X ATPase activity did not decrease in the presence

of the isolated TRPV4 intrinsic disordered region (hsV4 IDR), which consists of aa 1-149 of hsV4N, preceding the hsV4 ARD. As a control, the well-characterized *B. subtilis* ATPase BmrA was also supplemented with hsV4 ARD to rule out unspecific effects on the lactate dehydrogenase and pyruvate kinase involved in this assay. No decrease in BmrA ATPase activity was observed upon hsV4 ARD wt supplementation (see section 6.4, figure 6.3), supporting the direct interaction between hsV4 ARD and DDX3X. Nevertheless the question arose, why there is such a discrepancy between hsV4N and hsV4 ARD modulation of DDX3X ATPase activity. Cross-linking mass spectrometry (XL-MS) experiments with DSS-cross linked hsV4N and DDX3X (see figure 4.10) revealed cross-linking between K251 of hsV4 ARD and K511 in the C-terminal helicase domain (HelicC) of DDX3X in close proximity to motifs V (aa 501-505) and VI (aa 525-536), which are responsible for RNA recognition (motif V) and ATP-binding (motif VI).¹⁴⁴

Figure 4.10: **Cross-linking mass spectrometry (XL-MS) confirms a direct interaction between hsV4N and DDX3X.** Green bars indicate native lysine residues, whereas lysine residues involved in DSS-mediated cross-linking are additionally numbered. Black lines show cross-links including hsV4N K70 and DDX3X lysine residues, red lines cross-links between hsV4N K121 and DDX3X K491 and hsV4N K251 and DDX3X K511, respectively. XL-MS measurements were kindly carried out by M.Sc. [redacted] University of Konstanz)

XL-MS experiments of Dr. Benedikt Goretzki demonstrated an IDR-ARD interaction in the *G. gallus* (chicken) TRPV4 N-terminus (ggV4N) between distinct lysine residues, indicating these interactions not to be arbitrary but rather following certain preferred contact sites of the IDR with the ARD.²³ Amongst others, ggV4N showed an intra-domain interaction between K56^{IDR} and K237^{ARD}, which could be also detected in the corresponding lysine residues K70^{IDR} and K251^{ARD} in hsV4N (data not shown). It was previously shown that the TRPV4 N-termini of chicken and human share important conserved motifs like the prolines in the PRR and show overall similar behavior and structural features (sharing 84.27% amino acid identity), enabling to transfer *in vitro* studies of the N-termini between the species.²² Regarding this folding behavior of the IDR back to the ARD, preventing the ARD to interact with a distinct contact site with the DDX3X HelicC domain, the difference of ATPase activity modulation between hsV4N, IDR and hsV4 ARD could be explained. The interaction of the IDR itself seems not to play a role in

ATPase modulation of DDX3X. Inada *et al.* showed that hsV4 ARD is able to bind ATP, which induces conformational changes in fingers 2 and 3.²⁷

Figure 4.11: **hsV4 ARD interacts with duplex RNA (dxRNA)-bound DDX3X.** **A** Tryptophan fluorescence measurements of DDX3X and hsV4 ARD wt. **B** Tryptophan fluorescence measurements of DDX3X and hsV4 ARD wt in the presence of dxRNA. Each sample was additionally supplemented with 1 μ M ATP, as DDX3X requires ATP for RNA binding.¹⁴⁴ hsV4 ARD does not harbor tryptophan residues. DDX3X was used at a concentration of 3 μ M and hsV4 ARD at either 3 μ M (1:1 ratio) or 12 μ M (1:4 ratio). Indicated samples were supplemented with duplex RNA (dxRNA) to a final concentration of 1 μ M. Measurements with dxRNA were corrected due to the inner filter effect of supplemented dxRNA (see equations 4.1 and 4.2).¹⁴⁵ Error bars indicate SDs of three measurements of three independent DDX3X purifications for each condition. Used TRPV4 N-terminal constructs originated from one purification. Emission maxima (λ_{\max} in nm) are listed with SDs if applicable. x-axis = emission wavelength λ in nm, y-axis = fluorescence intensity in arbitrary units. **C** Topology model of recombinantly expressed and purified human DDX3X used for tryptophan fluorescence measurements, containing four tryptophan residues (indicated by pink bars). DEAD = DEAD domain (RecA-like domain 1), HELICc = C-terminal helicase domain (RecA-like domain 2). See figure 4.14 A for full-length DDX3X.

To exclude unspecific DDX3X ATPase activity modulation via interactions between the dxRNA phosphate groups and the basic surfaces of hsV4 ARD, tryptophan fluorescence measurements were carried out (figure 4.11). The DDX3X construct used here harbors four tryptophan residues (W127, W137, W421 and W570), whereas hsV4 ARD does not include any tryptophan residues, resulting in the DDX3X tryptophan residues to be the only reporters in these measurements. With tryptophan fluorescence it is possible to investigate the polarity of tryptophan environments in proteins, displayed by the position of the tryptophan residue emission maxima. Polar environments result in redshifted emission maxima, hydrophobic environments therefore in blueshifted maxima. Furthermore, the quantum yield and thus the emission intensity also depends on the tryptophan's direct environment, displaying higher emission intensities

of tryptophan residues in more apolar surroundings.¹⁴⁵ Due to inner filter effects (quenching of tryptophan fluorescence) of the supplemented dxRNA, the obtained fluorescence spectra were corrected according to Hellmann *et al.* with the following equations:¹⁴⁵

$$\text{Correction Factor (CF)} = \frac{F_W(x)}{F_W(0)} \quad (4.1)$$

The Correction Factor (CF) in equation 4.1 is obtained by the division of the fluorescence of a tryptophane solution with 1 μ M dxRNA ($F_W(x)$) by the fluorescence of a pure tryptophane solution ($F_W(0)$). The tryptophan concentration here was the same as used for DDX3X in the measurements (3 μ M). The corrected tryptophan fluorescence for DDX3X ($F_{\text{DDX3X, corrected}(x)}$) was then obtained by dividing the measured tryptophan fluorescence with dxRNA ($F_{\text{DDX3X}}(x)$) divided by CF (see 4.2).

$$F_{\text{DDX3X, corrected}(x)} = \frac{F_{\text{DDX3X}}(x)}{\text{CF}} \quad (4.2)$$

The displayed tryptophan fluorescence measurements suggest that hsV4 ARD binds to ATP and dxRNA-bound DDX3X. Intensity changes in figure 4.11 A are not considered significant, as more measurements have to be carried out to receive statistical relevant results with DDX3X and hsV4 ARD in the ratios 1:1 and 1:4, respectively. Emission spectra in figure 4.11 B hint to a dxRNA mediated interaction between DDX3X and hsV4 ARD. Upon dxRNA addition, the emission maximum significantly blueshifted in comparison to ATP-bound DDX3X in the absence of dxRNA from 348 nm to 338 nm, which implies a considerable polarity change of the DDX3X tryptophan residues towards a more hydrophobic environment. The crystal structures shown in figure 4.12 visualize the dramatic structural change and therefore the tryptophane residues' environmental change upon RNA binding in DDX3X.^{142,144} Addition of dxRNA lead to a significant emission intensity decrease, which can be explained by the quenching effect of RNA in tryptophane fluorescence measurements.^{146,147} Interestingly, upon hsV4 ARD supplementation, the DDX3X emission maxima gradually redshifted, suggesting a direct interaction between DDX3X and hsV4 ARD. Additionally, a dramatic emission intensity increase upon hsV4 ARD supplementation was detected, especially at a DDX3X:hsV4 ARD ratio of 1:4. These tryptophan residues environment changes indicate a direct hsV4 ARD interaction with DDX3X and not unspecific binding of dxRNA by hsV4 ARD.

Figure 4.12: **dsRNA binding changes the tryptophan environment in DDX3X dramatically.** **A** Crystal structures of human DDX3X in the apo state (left, PDB: 5E71)¹⁴² and bound to double-stranded RNA (right, PDB: 6O5F)¹⁴⁴. ATP-binding DEAD domain is colored in light blue, the c-terminal helicase domain (HelicC) in dark blue. **B** Topology model of recombinantly expressed and purified human DDX3X used for tryptophan fluorescence measurements, containing four tryptophan residues (indicated by pink bars). DEAD = DEAD domain (RecA-like domain 1), HELICc = C-terminal helicase domain (RecA-like domain 2). See figure 4.14 A for full-length DDX3X.

XL-MS measurements were carried out without any ATP or dxRNA supplementation, as these additions could have interfered the cross-linking reaction, showing that the DDX3X:hsV4 ARD interaction also occurs without these components. One main advantage of XL-MS is the possibility to capture PPIs, which are very weak and/or transient.⁸⁷ Therefore, the XL-MS results combined with the rather low-resolution spectroscopic and photometric measurements indicate that DDX3X also interacts with hsV4 ARD in the apo state *in vitro*, but that this interaction can be enhanced upon ATP- and dxRNA binding. As DDX3X showed higher \log_2 ratios in MS-measurements carried out in subchapter 4.1 with hsV4 ARD R232C compared to hsV4 ARD wt or hsV4N, suggesting elevated DDX3X-binding level in the presence of this mutation, complementary ATPase assays as in figure 4.9 were carried out with respective mutation bearing TRPV4 N-terminal constructs. Interestingly, both hsV4N R232C and hsV4 ARD R232C showed significantly higher ATPase inhibiting effects as their wild-typic complementaries (figure 4.13).

These results underline the trend that DDX3X ATPase activity inhibition by hsV4 ARD R232C is more enhanced than by hsV4N R232C. As Dr. Benedikt Goretzki suggested²³, the charge distribution in ggV4N probably modulates the interaction between IDR and ARD. The very N-terminal part of ggV4N is enriched with negatively charged residues, which could interact with the overall positively charged residues of the ARD finger 1 and 2. Arg232 in hsV4 ARD resides in finger 2 and furthermore builds a salt bridge to Glu183 in finger 1, which was observed in the crystal structure of the isolated hsV4 ARD.²⁷ The neutral mutation R232C could disrupt the overall basic patch in hsV4 ARD which might be required for the intra-domain IDR-ARD interaction. Additionally, the disruption of the R232-E183 salt bridge could influence the dynamics of finger 1 and 2 of hsV4 ARD, leading to altered conformational hierarchies in the IDR-ARD interaction. Thus, the R232C mutation could lead to a decreased IDR-mediated masking of the probable DDX3X interaction site of hsV4 ARD.

Figure 4.13: DDX3X ATPase activity inhibition is enhanced in the presence of neuropathy-causing TRPV4 R232C mutation. **A + B** An enzyme-coupled ATPase assay reveals an inhibitory effect of both, hsV4N R232C and hsV4 ARD R232C, onto the ATPase activity of DDX3X.⁸⁴ DDX3X was used at a concentration of 3 μ M and TRPV4 N-terminal constructs at 12 μ M, resulting into a 1:4 ratio. After 30 s samples were supplemented with ATP and after 5 min with duplex RNA (dxRNA), both at a final concentration of 1 μ M. ATPase activity was determined by an ATP-dependent enzyme-coupled oxidation from NADH to NAD⁺, resulting in an time-dependent absorption decrease at 340 nm. Measurements were normalized to DDX3X ATPase activity (DDX3X). Error bars indicate SDs of three measurements of three independent DDX3X purifications for each condition. Used TRPV4 N-terminal constructs originated from one purification. The TRPV4 intrinsic disordered region (IDR), consisting of aa 1-149 preceding the ARD of hsV4N, was kindly provided and fully characterized by Dr. [REDACTED]²³ and M. Sc. [REDACTED].¹⁴³ x-axis = time in s, y-axis = extinction at 340 nm in arbitrary units **C** DDX3X ATPase activity in the presence of several TRPV4 N-terminal constructs. Error bars indicate SDs of determined slopes after natural logarithmic conversion and linear regression.

Additionally to the Y2H screen showing direct interaction between the full-length TRPV4 channel and DDX3X, Donate-Macian *et al.* performed co-IPs with full-length TRPV4 and DDX3X co-transfected in HEK293 cells. It was shown that DDX3X immunoprecipitates with TRPV4 and *vice versa*. To evaluate these *in cellulo* experiments, co-IPs were performed with HEK293T

Chapter 4. Results

cells co-transfected with full length human TRPV4 with a c-terminal GFP-tag (hsTRPV4-cGFP) and full-length human DDX3X with a n-terminal V5-tag (hsDDX3X-nV5, see figure 4.14 A for a full-length DDX3X topology model of the here used construct compared to the recombinantly expressed and purified DDX3X used for the here shown *in vitro* experiments). Furthermore, to investigate the effects of TRPV4 disease-causing mutations on DDX3X interaction *in cellulo*, co-transfection and -IPs with hsTRPV4 R232C-cGFP and hsDDX3X-nV5 were also performed. Transfections with hsTRPV4 K276E-cGFP resulted in severe cell death (data not shown). Figure 4.14 B and C show two western blots after co-IPs. Both western blots showed co-IP of hsDDX3X-nV5 with hsTRPV4 R232C-cGFP. With hsTRPV4-cGFP, only a weak band for hsDDX3X-nV5 in figure 4.14 B was detected.

Figure 4.14: Co-immunoprecipitations (co-IPs) of full-length human TRPV4-cGFP and TRPV4 R232C-cGFP, respectively, in HEK293T cells show an increased DDX3X-V5 pulldown with the neuropathy-causing TRPV4-R232C mutation. A Topology models of human full-length TRPV4 constructs and DDX3X used for co-expression in HEK293T cells. For TRPV4, important N-terminal domains, namely the proline rich region (PRR), phosphoinositide-binding domain (PBD) and ankyrin repeat domain (ARD), are highlighted. GFP = Green-fluorescent protein, V5= V5-tag (single letter code: GKIPNPLLGLDST), NES = nuclear export sequence, eIF4E = binding site of transcription factor eIF4E, NTE= N-terminal extension, DEAD = DEAD domain (RecA-like domain 1), HELICc = C-terminal helicase domain (RecA-like domain 2), CTE = C-terminal extension.¹⁴⁸ **B + C** Two α-GFP co-IPs with full-length human TRPV4-cGFP and TRPV4 R232C-cGFP, respectively, co-transfected with hsDDX3X-nV5 in HEK293T cells show an increased hsDDX3X-nV5 pulldown with the neuropathy-causing TRPV4-R232C mutation. To rule out unspecific interactions, soluble GFP was co-transfected with respective TRPV4 construct. **D** Densitometric quantification of co-immunoprecipitated hsDDX3X-nV5, normalized to immunoprecipitated hsTRPV4-cGFP of respective condition. Error bars indicate SD. Densitometry was performed with Fiji.

Even though the amount of co-immunoprecipitated hsDDX3X-nV5 is low, the in the ATPase assays (figure 4.13) observed trend of a stronger DDX3X-TRPV4 R232C interaction compared to wild-type TRPV4 persisted. In the last few years, pathological stress granule formation more and more emerged to be one possible cause of neurodegenerative diseases such as the TRPV4-associated Charcot-Marie-Tooth Type 2C disease. These membraneless organelles form *in cellulo* upon oxidative and hyperosmotic stress, amongst others, as a consequence of stress-induced translational shutdown and polysome disassembly.^{121,149} Stress granules are composed mainly from RNA-binding proteins like DDX3X and form highly dynamic structures upon acute stress, whereas chronic cellular stress is proposed to induce pathologically stable complexes that might promote the formation of aggregates.^{149–151}

Based on the elevated DDX3X-TRPV4 R232C interaction shown in subchapter 4.1.2 and in figures 4.13 and 4.14, fluorescence microscopy experiments with HEK293T cells co-transfected with the same constructs used as in the co-IPs in figure 4.14 were performed to investigate probable foci formations of DDX3X in the presence of TRPV4 and/or neuropathy causing TRPV4 R232C (figure 4.15). Transiently transfected HEK293T cells showed expected subcellular localization of respective proteins, namely hsDDX3X-nV5 in the cytosol and hsTRPV4-cGFP in the plasma membrane. In the case of hsTRPV4 R232C-cGFP, beside the plasma membrane localization also GFP-containing foci were observed. For hsDDX3X-nV5 alone a uniform cytosolic distribution was observed, whereas in the presence of hsTRPV4-cGFP densifications formed. These hsDDX3X-nV5 densifications were more pronounced and spatially distinct as foci in the presence of hsTRPV4 R232C-cGFP. hsDDX3X-nV5 and hsTRPV4-cGFP or hsTRPV4 R232C-cGFP co-expression did not alter the subcellular localization of both TRPV4 constructs. These results indicate an influence of TRPV4 on DDX3X-containing foci formation *in cellulo*. Valentin-Vega *et al.* showed that medulloblastoma-associated mutations in DDX3X, leading to deficiency in RNA-stimulated ATP-hydrolysis of DDX3X, spur stress granule hyperassembly.^{119,142} Therefore, not only the increased basal Ca^{2+} influx levels due to the neuropathy causing R232C mutation could lead to abnormal stress granule formations, but also the elevated ATPase inhibition due to an increased DDX3X interaction with the mutated hsV4 ARD. Donate-Macian *et al.* showed a decreased DDX3X co-IP with TRPV4 in Huh7 cells

Figure 4.15 (*facing page*): **Fluorescence microscopy images of HEK293T cells co-transfected with TRPV4-GFP (green) and DDX3X-V5 (magenta) reveal cytosolic DDX3X densifications (white arrow heads), especially in the presence of TRPV4-R232C-GFP.** V5-tag of DDX3X was detected via mouse anti-V5 primary antibody and subsequent Alexa Fluor™647-coupled anti-mouse secondary antibody staining. Nuclei were stained with DAPI. Scale bar = 10 μm . Images were taken with a Zeiss Axio Observer Z1 inverted widefield microscope.

upon treatment with the TRPV4 activator GSK1016790A (GSK-101), inducing TRPV4-mediated Ca^{2+} -influx. Additionally, TRPV4-mediated Ca^{2+} -influx, activated either via hypotonicity or the TRPV4 agonist GSK-101, induced partial shuttling of DDX3X into the nucleus in HEK293 cells via a Ca^{2+} /Calmodulin-dependent pathway. This shuttling behavior was not observed with the gain-of-function R232C mutation in TRPV4 in this thesis (figure 4.15).^{54,136} In summary, the results by Donate-Macian *et al.* indicate a disruption of the TRPV4-DDX3X PPI upon TRPV4 activation.¹³⁶ In combination with the results shown in this thesis, the increased TRPV4 R232C-DDX3X PPI seems to be Ca^{2+} -influx independent, as TRPV4 R232C was previously shown to exhibit elevated basal Ca^{2+} -influx activity.⁵⁴ The TRPV4 R232C-DDX3X PPI seems to be elevated due to mutation-induced electrostatic and structural changes within and between the two proteins. These findings underline the importance of stress granule homeostasis and the severe consequences of dysregulation in stress granule dynamics, which ultimately leads to neuronal cell death.¹¹⁹ The data shown in this thesis reveal TRPV4 as a potential communication hub for downstream processes involved in stress granule formation.

4.3 It is all about humanity - an *in cellulo* study of the interaction between human TRPV4 and PACSIN1-3

Besides the six ankyrin repeats organized in an ankyrin repeat domain (ARD), the hsV4N contains a proline rich region (PRR, aa 132 – 144) which is necessary for the interaction with PACSIN3 (Protein kinase C and casein kinase substrate in neurons 3), one of the few known direct interactors of TRPV4.⁷⁰ All three PACSIN isoforms consist of a F-BAR domain, a linker domain and a SH3 domain, of which the latter interacts with the TRPV4 PRR (see figure 4.16 F).^{22,70,71} Previous experiments evaluated the physiological role of PACSIN3 in TRPV4 modulation, where it was shown that the relative plasma membrane amount of TRPV4 is enhanced by PACSIN3, but not by PACSIN1 and 2, despite of co-IPs of all three mouse PACSINs with rat TRPV4.⁷⁰ Furthermore, D'hoedt *et al.* showed that PACSIN3 desensitizes TRPV4 and inhibits its activation by cell swelling induced via a hypoosmotic solution and heat, but not by chemical stimuli like the known TRPV4 activator 4 α -phorbol 12,13-didecanoate (4 α -PDD). Although these previous experiments comprehensively evaluated the physiological role of PACSIN3 in TRPV4 modulation, data about the roles of PACSIN1 and PACSIN2 are lacking.^{70,71} Also, before mentioned experiments were performed with rodent proteins (mouse PACSINs and rat TRPV4 or mouse TRPV4) in a human expression system (HEK293T cells). To elucidate the role of all PACSINs in TRPV4 modulation, in this work human full-length PACSINs and TRPV4 were co-expressed in HEK293T cells to gain a comprehensive and species consistent view on the physiological role of these PPIs. Following the initial studies of D'hoedt *et al.*⁷¹ showing dampened TRPV4-mediated Ca²⁺-influx upon hypotonicity by PACSIN3 in HEK293T cells, a Fura-2 AM-based Ca²⁺-influx assay was performed (see figure 4.16 A). HEK293T cells co-transfected with human full-length TRPV4 and PACSIN1 or PACSIN3, respectively, show significant dampened TRPV4-mediated Ca²⁺-influx in comparison to cells transfected with TRPV4 alone or co-transfected with PACSIN2. Furthermore, PACSIN1 and PACSIN3 dampen the basal Ca²⁺-influx activity of TRPV4 (t=0). Figure 4.16 B shows that PACSIN1 and 3, but not PACSIN2, co-immunoprecipitate with TRPV4, which is in disagreement with the co-IPs performed with the rodent PACSIN orthologues and TRPV4.⁷⁰ As expression levels of all three PACSINs in figure 4.16 are on a comparable level, these results underline the difference of PPIs between protein orthologues across species, even in the context of high protein identities (see section 6.5).

Figure 4.16: Human PACSIN1 and 3, but not PACSIN2, dampen human TRPV4-mediated Ca^{2+} -influx in transiently co-transfected HEK293T cells upon hypotonicity. **A** HEK293T cells transiently co-transfected with TRPV4-FLAG and PACSIN1-3-V5, respectively, were loaded with the calcium indicator Fura-2 AM and treated with hypotonic saline (30 mM NaCl) at time = 0. Intracellular calcium levels were measured by acquiring 340 nm/380 nm ratio images every 10 s for 480 s. EV = transfection with empty vector. Averages represent $n = 3$, where each measurement was conducted with 4 coverslips with 20-30 cells per coverslip per condition. Error bars indicate SD. x-axis = time in s, y-axis = Fura 2-AM 340 nm/380 nm wavelength ratio. **B** HEK293T cells transiently co-transfected with TRPV4-FLAG and PACSIN1-3-V5, respectively, were loaded with the calcium indicator Fura-2 AM and treated with 30 nM of the TRPV4 agonist GSK-101 at $t = 0$. For more experimental details see subfigure A. **C** Representative α -FLAG co-immunoprecipitation of TRPV4-FLAG and PACSIN1-3-V5, respectively, co-transfected in HEK293T cells show co-immunoprecipitation of PACSIN1 and 3, but not PACSIN2, with TRPV4-FLAG. **D** Densitometric quantification of co-immunoprecipitated PACSINs, normalized to immunoprecipitated TRPV4-FLAG of respective condition. Paired two-tailed t-test, $n=3$ from three independent co-IPs, $*p \leq 0.05$. Error bars indicate SD. Densitometry was performed with Fiji. **E** Immunofluorescence images of HEK293T cells co-transfected with TRPV4-FLAG (red) and PACSIN1-3-V5 (green), respectively, show proper cellular distribution of overexpressed constructs with TRPV4-FLAG in the plasma membrane and PACSIN1-3-V5 in the cytosol. FLAG-tag was detected with rabbit α -FLAG and subsequent α -rabbit Alexa Fluor 555 staining. V5-tag was detected with mouse α -V5 and subsequent α -mouse Alexa Fluor 488 staining. Nuclei were stained with DAPI. Scale bar = 10 μm . Images were taken with a Zeiss LSM800 Confocal Microscope. **F** Topology model of expressed PACSIN constructs. V5= V5-tag (single letter code: GKPIPNPLLGLDST), FLAG = FLAG tag (single letter code: DYKDDDDK)

To confirm functional expression of TRPV4, complementary Ca^{2+} -influx experiments were performed with the potent TRPV4 agonist GSK-101, showing no PACSIN-mediated TRPV4 Ca^{2+} -influx dampening (see figure 4.16 C).^{70,152,153} Additionally, immunofluorescence images in figure 4.16 D show proper subcellular distributions of expressed constructs *in cellulo*.

PACSIN3 mRNA transcripts were mainly found in skeletal and heart muscle tissue, whereas PACSIN2 transcripts were detected ubiquitously and PACSIN1 transcripts showed neurospecificity.¹⁵⁴ Interestingly, co-expression of the neuropathy-causing TRPV4 R269C mutation and PACSIN1 showed a strong trend towards a loss of TRPV4-mediated Ca^{2+} -influx inhibition in HEK293T cells upon hypotonicity, whereas PACSIN3 still retained its desensitizing role in TRPV4 regulation (figure 4.17). In agreement with Woolums *et al.*, Ca^{2+} -influx experiments indicate higher basal TRPV4 R269C Ca^{2+} -influx activity compared to wild-typic TRPV4 ($t = 0$).⁵³ Despite the loss of the PACSIN1-desensitizing function upon stimuli induced TRPV4 R269C activation, co-expression of PACSIN1 with TRPV4 R269C still seems to dampen basal TRPV4 mediated Ca^{2+} -influx ($t=0$). To substantiate these trends, additional Ca^{2+} -influx assays are required. A first co-IP hints towards a loss of PACSIN1-binding to TRPV4 R269C (figure 4.17 B). These results indicate a neuron-specific consequence of the neuropathy-causing TRPV4 R269C mutation, also regarding the above mentioned tissue specific mRNA transcription of the three PACSIN isoforms. The mechanisms of PACSIN-mediated TRPV4 modulation still remain elusive until this date. Neurons are more vulnerable towards chronic Ca^{2+} -influx compared to other cell types due to their unique cellular structure, which lead to higher sensitivity towards Ca^{2+} -dyshomeostasis with excitotoxicity as a possible consequence.¹⁵⁵ As the desensitizing function of PACSIN1 precedes upon the TRPV4 R269C mutation in neurons, other tissues are possibly still able to regulate TRPV4-mediated Ca^{2+} -influx via PACSIN3 and/or other until now not known TRPV4 regulating mechanisms.

To shed light on the PPI between the PACSINs and the TRPV4 PRR, in chemical shift perturbation assays using nuclear magnetic resonance (NMR) spectroscopy, Goretzki *et al.* probed structural changes of the different PACSIN SH3 domains upon interacting with the TRPV4-PRR.²² All three SH3 domains interact with the TRPV4-PRR in a highly comparable manner. These experiments showed that the SH3 domains of PACSIN1, 2 and 3 interact with the TRPV4-PRR through the same binding interfaces and have highly similar binding affinities. However, co-IPs (figure 4.16 B) showed that PACSIN3 binds better to TRPV4 than PACSIN1, and that PACSIN2 does not bind to TRPV4 *in cellulo* at all. This strongly hints towards a difference in the TRPV4-PACSIN3 interaction compared to its interaction with PACSIN1 in the context of full-length PACSINs and full-length TRPV4.

Figure 4.17: **Human PACSIN1 does not dampen TRPV4-mediated Ca^{2+} -influx in HEK293T cells transiently transfected with TRPV4 R269C upon hypotonicity.** **A** HEK293T cells transiently co-transfected with TRPV4-FLAG or neuropathy-causing TRPV4 R269C-FLAG and PACSIN1-3-V5, respectively, were loaded with the calcium indicator Fura-2 AM and treated with hypotonic saline (30 mM NaCl) at time = 0. Intracellular calcium levels were measured by acquiring 340 nm/380 nm ratio images every 10 s for 480 s. EV = transfection with empty vector. Averages represent $n = 2$, where each measurement was conducted with 4 coverslips with 20-30 cells per coverslip per condition. x-axis = time in s, y-axis = Fura 2-AM 340 nm/380 nm wavelength ratio. **B** α -FLAG co-immunoprecipitation of neuropathy-causing TRPV4 R269C-FLAG and PACSIN1-3-V5, respectively, co-transfected in HEK293T cells show only co-immunoprecipitation of PACSIN3 with TRPV4, but not PACSIN1 and 2.

Since Goretzki *et al.* have excluded the SH3 domain as the origin of these differences, the next step was to focus on the F-BAR domains. For this, the three F-BAR domains of PACSIN1-3 were exchanged while retaining the linker and SH3 domain of the original PACSIN via Gibson Assembly.^{79,80} Of these originally six cloned constructs, only three showed expression in HEK293T cells (see figure 4.18 C for detailed chimera construct composition). Figure 4.18 A shows the results of Fura-2 AM-based Ca^{2+} -influx assays performed with HEK293T cells co-transfected with TRPV4 and respective PACSIN chimeras treated with hypotonic saline. Both PACSIN chimeras that combine the PACSIN1 linker and SH3 domain with either the PACSIN2 or PACSIN3 F-BAR domain (PACSIN2+1 and PACSIN3+1, figure 4.18 C), respectively, show no regulation of TRPV4-mediated Ca^{2+} -influx upon hypotonicity. Strikingly, PACSIN chimera PACSIN2+3, consisting of the PACSIN2 F-BAR domain with PACSIN3 linker and SH3 domain, shows comparable Ca^{2+} -influx dampening to PACSIN3-mediated dampening (figure 4.16 A). Co-IPs with TRPV4-FLAG and N-terminally V5-tagged PACSIN chimeras could not show a pull-down of any PACSIN chimera with TRPV4. Immunofluorescence images (figure 4.18 D) confirmed proper cellular distribution of the PACSIN chimeras in the cytosol and TRPV4 in the plasma membrane.

Figure 4.18: **PACSIN chimeras hint towards different regulation modes between PACSIN1 and PACSIN3 on TRPV4-mediated Ca^{2+} -influx in HEK293T cells.** **A** HEK293T cells transiently co-transfected with TRPV4-FLAG and respective PACSIN chimera shown in subfigure C, respectively, were loaded with the calcium indicator Fura-2 AM and treated with hypotonic saline (30 mM NaCl) at time = 0. Intracellular calcium levels were measured by acquiring 340 nm/380 nm ratio images every 10 s for 480 s. EV = transfection with empty vector. Averages represent n = 3, where each measurement was conducted with 4 coverslips with 20-30 cells per coverslip per condition. Error bars indicate SD. x-axis = time in s, y-axis = Fura 2-AM 340 nm/380 nm wavelength ratio. **B** Representative α -FLAG co-immunoprecipitation of TRPV4-FLAG and respective PACSIN chimera (see subfigure C) co-transfected in HEK293T cells show no co-immunoprecipitation of the PACSIN chimeras with TRPV4-FLAG. **C** Topology model of expressed PACSIN chimeras. For this the three F-BAR domains of PACSIN1-3 were exchanged while retaining the linker and SH3 domain of the original PACSIN. Of these originally six cloned constructs, only the pictured three showed expression in HEK293T cells. V5= V5-tag (single letter code: GKIPNPPLGLDST), FLAG = FLAG tag (single letter code: DYKDDDDK). **D** Immunofluorescence images of HEK293T cells co-transfected with TRPV4-FLAG (red) and respective PACSIN chimera show proper cellular distribution of overexpressed constructs with TRPV4-FLAG in the plasma membrane and the PACSIN chimeras in the cytosol. FLAG-tag was detected with rabbit α -FLAG and subsequent α -rabbit Alexa Fluor 555 staining. V5-tag was detected with mouse α -V5 and subsequent α -rabbit Alexa Fluor 488 staining. Nuclei were stained with DAPI. Scale bar = 10 μ m. Images were taken with a Zeiss LSM800 Confocal Microscope.

These results indicate different TRPV4-regulation modes between PACSIN1 and PACSIN3. Whereas PACSIN1 seems to need its F-BAR domain, PACSIN3 seems to regulate TRPV4-mediated Ca^{2+} -influx either F-BAR-independently or the PACSIN2 F-BAR domain is sufficient enough to substitute the PACSIN3 F-BAR domain (see also section 6.5 for multiple sequence alignment between human PACSIN F-BAR domains, indicating a higher sequence identity between the PACSIN2 F-BAR domain and PACSIN3 F-BAR domain than between the PACSIN1 F-BAR domain and PACSIN3 F-BAR domain). Cuajungco *et al.* showed that PACSIN3 lacking

the F-BAR domain lost its ability to dampen TRPV4-mediated Ca^{2+} -influx upon hypotonicity in HEK293T cells.⁷⁰ This would hint towards the ability of the PACSIN2 F-BAR domain to substitute the PACSIN3 F-BAR domain. BAR domain-containing proteins like PACSIN1-3 are known to induce various forms of membrane deformations.^{156,157} Membrane deformation experiments conducted by Goh *et al.* showed that the isolated F-BAR domains of PACSIN2 and PACSIN3 produced similar membrane morphologies after incubation with liposomes. Whereas PACSIN2 and 3 F-BAR proteins mainly induced formation of vesicular structures and wide tubules, the PACSIN1 F-BAR domain additionally induced narrow tubule formation. Additionally, Bai *et al.* showed in liposome tubulation assays that PACSIN3 induced low curvature tubulation with mainly tubule formation diameters from 90 nm to 110 nm, whereas PACSIN1 also additionally formed high curvature tubules, ranging from 10 nm to 200 nm. In this case, PACSIN2 again showed an intermediate behavior between PACSIN1 and 3, where PACSIN2-induced tubules showed a diameter range like PACSIN1, but the relative number of low-curvature tubes is higher compared to PACSIN1. It was shown previously that TRPV4-activation indeed is dependent from the surrounding membrane fluidity and stiffness and thus different degrees of membrane curvatures could also play a regulatory role in TRPV4 regulation.¹⁵⁸ As the different PACSIN isoforms serve different levels and forms of membrane deformations, PACSIN isoform dependent TRPV4 regulation via the F-BAR mediated membrane microenvironment seems to be an explanation for the possible different TRPV4-regulation modes between PACSIN1 and 3.^{156,157,159,160} These findings also underline the probable ability of the PACSIN2 F-BAR domain to induce similar membrane curvatures like the PACSIN3 F-BAR domain. Therefore the PACSIN2 F-BAR domain may probably serve comparable local membrane environments for TRPV4 in the context of the PACSIN chimera 2+3.^{156,160} Membrane deformation activity assays with all three murine full-length PACSIN isoforms showed reduced membrane deformation activity compared to the isolated F-BAR domains, whereby full-length PACSIN1 showed a significantly higher activity loss than PACSIN3. PACSIN2 showed again an intermediate behavior, where an activity decrease was also observed, but this decrease was not as pronounced as for PACSIN1. Membrane deformation activity reduction might occur due to the autoinhibition by the SH3 domain binding on the F-BAR domain, preventing the F-BAR domain to interact with membranes. This particular autoinhibition was shown for PACSIN1 in a X-ray crystal structure of murine PACSIN1 (PDB: 2X3X), where a negatively charged triple motif (Q396, E397, E400) in the SH3 domain interacts with a basic lysine patch (K141, K145, K148) in the F-BAR domain. This was confirmed with site-directed mutagenesis with subsequent pull-down assays *in cellulo*.^{156,157} As the substrate-binding site of the SH3 domain overlaps with the SH3/F-BAR

domain interacting site, it was shown that the dynamin-PRR interrupts PACSIN1 autoinhibition and induces PACSIN1-mediated lipid tubulation.¹⁵⁶ This autoinhibition mechanism was also proposed for PACSIN2 and 3, as the SH3 and F-BAR domains amongst the isoforms are highly conserved, including the SH3/F-BAR domain interaction sites. Indeed, Goretzki *et al.* could show via NMR spectroscopy that the PACSIN3 SH3 domain interacts with the PACSIN3 F-BAR domain and that a QEE/RRR mutation in the PACSIN3 SH3 domain abrogated this interaction. Furthermore, the interaction between PACSIN3 SH3 and F-BAR seemed to be comparably weak and could be released with a TRPV4-PRR containing peptide in a similar manner to the dynamin-PRR-mediated autoinhibition-release of PACSIN1.^{23,156} The strength between the SH3 and F-BAR domain interaction of PACSIN1 and 2 still have to be determined and variations in respective K_D values could serve as another explanation for the different TRPV4-mediated behaviors between the three PACSIN isoforms and the possible ability of the PACSIN2 F-BAR domain to substitute the PACSIN3 F-BAR domain in the chimera PACSIN2+3. Expression of the PACSIN chimera consisting of PACSIN1 F-BAR domain and PACSIN3 linker and SH3 domain was not possible. Therefore it remains elusive, if the PACSIN1 F-BAR domain could also substitute the PACSIN3 F-BAR domain like occurred in PACSIN chimera 2+3.

Another explanation for the different TRPV4-regulation outcomes of the PACSIN chimeras could be different protein interactomes of PACSIN1 and 3, due to their different tissue distributions and minor differences in amino acid sequences.¹⁵⁴ Goretzki *et al.* proposed that PACSIN3 possibly binds to TRPV4 as a dimer, where the F-BAR domains mediate the PACSIN3 dimerization. One SH3 domain therefore would interact with the TRPV4 PRR, whereas the other SH3 domain could recruit additional TRPV4 binding partners.

Furthermore, PACSIN3 is the only PACSIN isoform that contains a proline rich region in its linker region (aa 337-345), with which other proteins could interact with. PACSIN chimera 3+2 thus seems still to be able to bind to the TRPV4 PRR via its SH3 domain, exposing the PACSIN3 PRRs in the linker domains and the other SH3 domain for further protein interactions to form a multicomponent TRPV4 signaling complex. This could be an additional determinant for a PACSIN3- and therefore tissue specific protein interactome, which leads to a robust PACSIN3-TRPV4 interaction, whereas PACSIN1 loses its binding and consequently TRPV4 regulation ability in the presence of the neuropathy-causing TRPV4 R269C mutation. Expression levels of the PACSIN chimeras in HEK293T cells were significantly lower compared to wild-type PACSIN1-3 (see figure 4.16 B), which could also be a reason for the missing co-IP of any of the PACSIN chimeras with TRPV4. Low-affinity or transient PPIs may not be detected in co-IPs, as extensive washing and mechanical/chemical stresses during the experiment could

disrupt the PPI of the target complex. Therefore it would still be possible that the chimera PACSIN2+3 still directly binds to TRPV4 via its SH3 domain *in cellulo*, leading to a TRPV4 regulation. This would indicate that already low amounts of a TRPV4-regulating PACSIN isoforms/chimera are sufficient to achieve TRPV4-mediated Ca^{2+} -influx dampening and also explain the similar Ca^{2+} -influx dampening effect of PACSIN1 and PACSIN3 (figure 4.16 A) even though the TRPV4-PACSIN1 interaction seems to be weaker in the context of HEK293T cells (figure 4.16 B).

4.4 Small but powerful - the small GTPase RhoA interacts with the TRPV4 Ankyrin Repeat Domain

Parts of this chapter were published in: McCray, B.A., Diehl, E. *et al.* Neuropathy-causing TRPV4 mutations disrupt TRPV4-RhoA interactions and impair neurite extension. *Nat Commun* **12**, 1444 (2021).⁶⁹

The author of the present thesis (Erika Diehl) contributed purification, characterization and nuclear magnetic resonance (NMR) spectroscopy-based PPI studies between recombinantly expressed ¹⁵N-RhoA and hsV4 ARD wt as well as hsV4 ARD R269C.

TRPV4 modulates cell morphology and stiffness via cytoskeleton components, namely microtubules and actin scaffolds.^{69,161–165} A generic bottom-up proteomics approach, conducted by MD [REDACTED] (RG [REDACTED], Department of Neurology, Johns Hopkins University School of Medicine) with immunopurified human TRPV4-FLAG overexpressed in HEK293T cells indicated the small GTPase RhoA as a putative direct TRPV4 interactor.⁶⁹ These data complemented the recently published TRPV4-RhoA interaction identified via a Y2H screen.¹³⁶ RhoA itself is a pivotal regulator of the actin cytoskeleton, inducing stress fiber formation, for example.^{166–168} Therefore a possible direct PPI and actin regulating interplay between TRPV4 and RhoA was investigated and if these putative interactions were aberrant in the presence of disease-causing mutations of TRPV4. MD [REDACTED] could show with comprehensive co-IP studies in HEK293T and MN-1 (a murine cholinergic motor neuron cell line) cells, that TRPV4 pulls down RhoA and *vice versa*. Furthermore, co-IPs of MN-1 cells transiently transfected with TRPV4 and inactive RhoA-GFP (T19N), or constitutively active RhoA-GFP (Q63L) demonstrated that TRPV4 interacts with inactive, GDP-bound RhoA T19N, but not active, GTP-

Figure 4.19 (*facing page*): **Purification of hsV4 ARD wt, hsV4 ARD R269C and ¹⁵N-isotope labeled human RhoA (¹⁵N-RhoA)**. **A** Schematic topology model of hsV4 ARD wt, hsV4 ARD R269C and ¹⁵N-RhoA used for NMR spectroscopy measurements. His₆ = hexa-histidine tag (single letter code: HHHHHH), TEV = Tobacco Etch Virus Cleavage Site (single letter code: ENLYFQG). His₆-tags with preceding or subsequent TEV Cleavage Site were removed. **B** SEC purifications of ¹⁵N-RhoA, hsV4 ARD wt and R269C. SEC runs were performed with a HiLoad Superdex 75 pg preparative SEC column. Inlets show Coomassie stained 15% SDS-PAGEs of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbance at 280 nm, M = marker. **C** For ¹⁵N-RhoA, the intrinsic GTPase activity was determined via the luminescence-based GTPase-Glo Assay. GTPase activity is inversely correlated to measured luminescence intensity. A paired two-tailed t-test with 3 independent measurements including 4 technical replicates was performed, ***p < 0.001. Error bars indicate SD. **D + E** Far UV CD spectra of purified hsV4 ARD wt and hsV4 ARD R269C as well as ¹⁵N-RhoA, respectively. Spectra were measured at 293 K and proteins were used at 1 μM concentration in RhoA SEC buffer with a final concentration of 20 mM NaCl. **F** Secondary structure prediction of shown far UV CD spectra shown in subfigures D and E, performed with CAPITO.⁹³ The predicted α-helix/β-sheet/random coil content of the purified proteins is for hsV4 ARD wt 78%/0%/22%, hsV4 ARD R269C 68%/0%/32% and ¹⁵N-RhoA 27%/24%/49%. y-axis: mean residue ellipticity $[\Theta]_{\text{mrw},\lambda}$ in 10⁻³ deg cm² dmol⁻¹, x-axis: wavelength λ in nm.

bound RhoA Q63L.¹⁶⁹ These results were further confirmed with Co-IPs in the presence of either excess GDP or an unhydrolyzable GTP analog (GTP γ S) to favor the inactive or active form of RhoA. Additionally, co-IPs with immunopurified RhoA-myc and recombinantly expressed, purified human TRPV4 N-terminus (hsV4N) and ARD (hsV4 ARD), respectively, indicated a direct interaction between these proteins. Further co-IPs in transiently transfected MN-1 cells showed an abolished TRPV4-RhoA PPI in the presence of neuropathy-causing TRPV4 mutants (R232C, R237L, R269C, R315W), but not skeletal dysplasia-causing mutations (I331F, D333G). These neuropathy-mutant PPI disruptions were shown to be TRPV4-channel activity independent, as neither the TRPV4 antagonist HC-067047 (HC-067) nor the pore-blocking M680K mutation restored the PPI between RhoA and TRPV4 harboring respective neuropathy-causing mutations.

Figure 4.20: **NMR experiments revealed an decreased PPI between ^{15}N -RhoA and the neuropathy-causing mutation R269C in hsV4 ARD.** **Left:** Representative 1D projection of ^1H resonances from 2D ^1H - ^{15}N NMR spectra of ^{15}N -RhoA (grey) and in the presence of either hsV4 ARD (blue) or hsV4 ARD R269C (red). Stronger signal decreases for ^{15}N -RhoA in the presence of hsV4 ARD versus neuropathy mutant R269C indicate a decreased interaction between ^{15}N -RhoA and mutant ARD. **Right:** Sections of 2D ^1H - ^{15}N -NMR HSQC spectra of ^{15}N -RhoA: Overlay of spectra of ^1H - ^{15}N -RhoA 2D HSCQs of ^{15}N -RhoA on its own (grey) in the presence of hsV4 ARD (blue, upper right) show line broadening, indicating the formation of a high molecular weight complex. In contrast, addition of hsV4 ARD R269C (red, lower right) shows only minor effects on the ^{15}N -RhoA spectrum. ^{15}N -RhoA backbone NMR assignments were transferred from previously published data¹⁷⁰. NMR spectra were recorded on a Bruker 600 MHz spectrometer equipped with a cryogenic triple probe at 298.15 K and processed using Bruker TopSpin 3.2.

Due to the clustering of investigated neuropathy-causing TRPV4 mutations in the TRPV4 ARD (hsV4 ARD), the author of this thesis examined the direct PPI between recombinantly expressed and purified ^{15}N -RhoA and wild-type hsV4 ARD (hsV4 ARD wt) as well as hsV4 ARD R269C neuropathy mutant (hsV4 ARD R269C) via nuclear magnetic resonance (NMR) spectroscopy. To characterize this PPI in detail, ^1H , ^{15}N NMR measurements of RhoA in the presence of hsV4 ARD and hsV4 ARD harboring the neuropathy-causing mutation R269C (hsV4 ARD R269C) were performed. For this, recombinantly expressed hsV4 ARD and hsV4 ARD R269C, as well as ^{15}N -labeled human GDP-bound RhoA (hereafter referred to as ^{15}N -RhoA) were purified (see subsection 3.7.5). Recombinant proteins showed the expected molecular weights via SDS-PAGE with subsequent Coomassie-staining (figure 4.19 **A** inlet) and secondary structures determined by CD spectroscopy (figure 4.19 **D** and **E**). Additionally, ^{15}N -RhoA showed enzymatic functionality in a luminescence-based GTPase assay (figure 4.19 **F**). After confirmation of the protein integrity, two-dimensional ^1H , ^{15}N -NMR spectra of ^{15}N -RhoA were recorded (see section 6.6 figures 6.4 and 6.5 for full spectra). The obtained spectra agreed with previously published NMR data (BMRB:16668)¹⁷⁰ and allowed a backbone resonance assignment transfer of 93.6 %.

Figure 4.21: **Relative signal intensity changes of RhoA in the presence of unlabeled hsV4 ARD wt and R269C, respectively.** The largest decrease in signal intensity accounted for the E54 residue in ^{15}N -RhoA, and a smaller decrease in E47, indicated by arrow heads. NBS = Nucleotide binding site, Switch 1 and 2 = Switch 1 and 2 loop, 2σ = two SDs

To map the hsV4 ARD binding site on ^{15}N -RhoA, spectra were recorded in the presence of either hsV4 ARD or hsV4 ARD R269C (see figure 4.20). Signal intensities of ^{15}N -RhoA resonances decreased significantly in the presence of hsV4 ARD, indicating formation of a large molecular complex between hsV4 ARD (29.3 kDa) and RhoA (21.8 kDa). Addition of hsV4 ARD R269C did not lead to such strong signal intensity decreases, indicating a reduced affinity for ^{15}N -RhoA. To identify the ^{15}N -RhoA residues that are strongly affected by the interaction with hsV4 ARD, the relative signal intensity for every residue in the ^{15}N -RhoA NMR spectra were determined (figure 4.21). In total, peaks corresponding to 20 residues in ^{15}N -RhoA exhibited peak

integral decreases greater than two standard deviations (2σ) in the presence of hsV4 ARD, whereas only two residues showed this decrease with hsV4 ARD R269C. This is also reflected in the mean relative signal intensity change of ^{15}N -RhoA in the presence of hsV4 ARD versus hsV4 ARD R269C (figure 4.22, right).

Mapping the affected residues onto the crystal structure of GDP-bound RhoA (PDB: 1FTN)¹⁷¹ revealed that the interswitch and switch II regions of ^{15}N -RhoA are primarily involved in hsV4 ARD binding (figure 4.22, left). The switch regions of RhoA are important regulatory sites within the small GTPase which are sensors whether RhoA is in its GDP or GTP-bound state by changing their conformational state upon the presence of hydrogen bonds to the γ -phosphate in GTP ("loading-spring" mechanism). Depending on the switch conformations, interaction of downstream effectors like Rho GDP dissociation inhibitors (RhoGDIs) and Rho guanine nucleotide exchange factors (RhoGEFs) are regulated.¹⁶⁹ The largest decrease in signal intensity accounted for the E54 residue in ^{15}N -RhoA, and a smaller decrease in E47, suggesting these residues might be particularly important in TRPV4 binding (see figure 4.21, indicated by arrow heads). These glutamic acids are unique to RhoA and are not present in the related Rho

Figure 4.22: **Interaction sites of hsV4 ARD with ^{15}N -RhoA.** *Left:* NMR signal intensities in the presence of hsV4 ARD mapped on a crystal structure of GDP-bound human RhoA (PDB: 1FTN)¹⁷¹. Residues with significant decreases in signal intensity (indicated in dark purple) are predominantly localized in the RhoA switch regions. White parts correspond to residues for which no peaks could be identified in the measured ^1H - ^{15}N 2D HSQC spectra. *Right:* Average integral change of ^{15}N -RhoA residues in the presence of hsV4 ARD or hsV4 ARD R269C. Error bars indicate SEM.

GTPases Rac1 and Cdc42, consistent with the results demonstrating specificity for interaction of TRPV4 with RhoA and not Rac1 or Cdc42.⁶⁹ Mutation of E54 to A completely abolished the interaction of RhoA with TRPV4 in co-IPs conducted by MD Brett A. McCray, suggesting that E54 may be important for electrostatic interaction with positively charged arginine residues

within the hsV4 ARD that appear to be critical for RhoA binding.⁶⁹ Both mutants, E47 and E54, showed preserved interaction with RhoGDI, indicating that they were properly folded and functional. Our observations thus provide a potential structural explanation for the disruption of RhoA interaction by neuropathogenic mutations within hsV4 ARD. MD Brett A. McCray showed

via live Ca^{2+} -influx assays and co-IPs with transiently transfected MN-1 cells, that RhoA binding results in suppression of TRPV4 channel activity but also to RhoA inhibition. Activation of TRPV4 with the potent TRPV4 agonist GSK-101 in transfected HEK293T cells lead to RhoA activation and cytoskeletal changes. The regulation of cell morphology by an interplay between TRPV4 and RhoA was furthermore investigated by neurite-like outgrowth length quantification of MN-1 cells. MN-1 cells transfected with TRPV4 alone showed pronounced neurite-like outgrowth, whereas the neuro-pathy-causing R237L mutation failed to promote neurite-like outgrowth in MN-1 cells. Co-expression of RhoA with TRPV4 therefore strongly inhibited this TRPV4-mediated neurite-like outgrowth, which was rescued by RhoA inhibition of the potent and specific RhoA inhibitor exoenzyme C3 transferase. Strikingly, also the neuropathy-causing mutation TRPV4 R237L phenotype could be partially rescued via RhoA inhibition, indicating that elevated RhoA activity due to interrupted RhoA-TRPV4 interaction contributes to pathological neurite-growth outcomes in TRPV4-caused neuropathies. This hypothesis was tested *in vivo* with a *D. melanogaster* model where it was found that expression of the *Drosophila* RhoA ortholog Rho1 by expression of dominant negative Rho1 T19N rescued neuronal degeneration with expression of neuropathy mutant TRPV4 R269C.

Within this cooperation, RhoA was identified as a direct interactor of TRPV4 with its ankyrin repeat domain, a notorious hot-spot for disease-causing mutations in TRPV4. RhoA was identified as a mediator of TRPV4-induced cell structure changes and the here described findings strongly hint towards that disruption of TRPV4-RhoA binding is one determinant of tissue-specific toxicity of TRPV4 neuropathy mutations.

4.5 All or nothing - interaction of ITCH requires the full TRPV4

N-terminus *in vitro*

Ubiquitination and deubiquitination of transmembrane proteins are key mechanisms in regulating their surface expression. Wegierski *et al.* showed that ITCH-mediated TRPV4 ubiquitination does not increase TRPV4 degradation but decreases the TRPV4 amount in the plasma membrane.¹⁷² It was shown that this ubiquitination took place at the TRPV4 N-terminus and not the C-terminus by overexpressing the respective FLAG-tagged cytosolic TRPV4 domain along with ITCH in HEK293T cells with subsequent western blotting of the cell lysates against FLAG and ubiquitin. As ITCH harbors four WW domains which are hypothetically able to interact with the TRPV4 PRR, these results suggested a direct interaction between ITCH and TRPV4, even though the cell lysate could have provided additionally required adaptor proteins for a proper PPI between ITCH and the TRPV4 N-terminus. Shukla *et al.* showed a β -arrestin 1 mediated ubiquitination and functional down-regulation of TRPV4 via an angiotensin I mediated AT1aR activation in HEK293T cells, indicating that β -arrestin 1 is required for a GPCR-regulated ITCH-mediated TRPV4 ubiquitination.¹⁷³

To investigate a possible direct interaction between ITCH and the human TRPV4 N-terminus (hsV4N) *in vitro*, recombinantly expressed human full-length ITCH was successfully purified for the first time to date (see figure 4.23 and subsection 3.7.7). To distinguish possible minimal binding sites within hsV4N, hsV4N ARD and hsV4N ARD with the PRR (hsV4 ARD-PRR) were also recombinantly expressed and purified (see subsection 3.7.1 and 3.7.2). All proteins showed expected molecular weights and secondary structures determined by CD spectroscopy

Figure 4.23 (*facing page*): **Purification of recombinant TRPV4 N-terminal constructs and human ITCH.** **A** Topology model of recombinantly expressed TRPV4 N-terminal constructs and human ITCH. His₆ = hexa-histidine tag (single letter code: HHHHHH), TEV = Tobacco Etch Virus Cleavage Site (single letter code: ENLYFQG), C2 = C2 domain, WW1+2 = WW domains 1 and 2, WW3+2 = WW domains 3 and 4, HECT = homologous to E6-AP C-terminus domain. His₆-tags with preceding or subsequent TEV Cleavage Site were removed. **B** SEC purification of full-length human ITCH. **C** SEC purifications of TRPV4 N-terminal constructs and ITCH. SEC runs were performed with either a HiLoad Superdex 200 or a HiLoad Superdex 75 pg preparative SEC column. Inlets show Coomassie stained 15% SDS-PAGEs of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbance at 280 nm, M = marker. **D** Far UV CD spectrum of full-length human ITCH. **E** Comparison of far UV CD spectra of purified TRPV4 N-terminal constructs. Spectra were measured at 293 K and proteins were used at 1 μ M concentration in either SEC Buffer with a final NaCl concentration of 30 mM (TRPV4 N-terminal constructs) or ITCH SEC buffer with a final concentration of 20 mM NaCl (ITCH). Inlets show secondary structure prediction performed with CAPITO.⁹³ The predicted α -helix/ β -sheet/random coil content of the purified proteins is for hsV4N 53%/0%/47%, hsV4 ARD-PRR 60%/0%/40%, hsV4 ARD 68%/0%/32% and ITCH 29%/20%/51%. x-axis: mean residue ellipticity ($[\Theta]_{mrw,\lambda}$) in 10⁻³ deg cm² dmol⁻¹, y-axis: wavelength λ in nm.

(see figures 4.23 A-E). The topology model in figure 4.23 A shows the domains full-length ITCH is harboring. Besides the already mentioned WW-domains, ITCH consists of a C2 and catalytically active HECT (homologous to E6-AP C-terminus) domain. C2 domains bind phospholipids for (plasma) membrane localization, either in Ca^{2+} dependent or Ca^{2+} independent manner, depending on the C2 domain family.¹⁷⁴ The catalytic HECT domain interacts with E2 ligases to obtain ubiquitin via trans-thioesterification and ultimately carries out the ubiquitination of substrate proteins.^{174,175} Zhu *et al.* provided the until to date only near-full length structure of ITCH via X-ray crystallography. However, the murine construct is lacking the N-terminal C2 domain ($\Delta\text{C2-ITCH}$) and WW3+4 are not resolved (PDB:5XMC).¹⁷⁵ Nevertheless, this murine $\Delta\text{C2-ITCH}$ structure is consistent with individual resolved structures of WW1+2 and HECT domains. The structure of Zhu *et al.*, combined with several resolved structures of the isolated domains, revealed an overall α -helical fold for the HECT domain, whereas the C2 and WW domains exhibit β -sheet folds.¹⁷⁵⁻¹⁷⁷ Enzymatic activity of purified ITCH was shown in an *in vitro* ubiquitination assay (figure 4.25 A). The putative complex formation between ITCH and respective TRPV4 N-terminal construct was probed via Blue-native PAGE (BN-PAGE). For hsV4N a complex at approx.150 kDa could be observed, which corresponds to an ITCH (approx.100 kDa)-hsV4N (approx.50 kDa) complex with a stoichiometry of 1:1. To confirm this, respective band was cut out (figure 4.24 B, red square) and mass spectrometric measurements were carried out (Johns Hopkins Mass Spectrometry and Proteomics Facility), confirming the presence of both proteins in indicated band. These results show that ITCH physically interacts with hsV4N, but not with hsV4 ARD and hsV4 ARD-PRR. Cross-link mass spectrometry (XL-MS) measurements with hsV4N and ITCH confirmed this direct PPI and also hint towards the requirement of full hsV4N for the interaction with ITCH (figure 4.24 C). Surprisingly, no lysine residues between hsV4N and the ITCH HECT domain were cross-linked. The ITCH HECT domain harbors the enzymatic activity site to receive ubiquitin from E2 ligases and to transfer this ubiquitin via trans-thioesterification to the target protein.^{178,179} Also, no cross-links between the hsV4N PRR and ITCH were detected, underlining the results of shown BN-PAGE results, that the full hsV4N is involved in the PPI (figure 4.24). To determine if ITCH is also able to ubiquitinate hsV4N *in vitro*, an ubiquitination assay with subsequent SDS-PAGE and Coomassie staining was performed with ITCH and respective hsV4N constructs (figure 4.25).

Figure 4.24: **ITCH and hsV4N are direct interaction partners.** **A** α-myc immunoprecipitation of ITCH-myc shows co-immunoprecipitation of TRPV4-FLAG co-transfected in HEK293T cells and confirms ITCH as a part of the TRPV4 interactome^{172,173} **B** Blue-native PAGE with purified TRPV4 N-terminal constructs and ITCH (see figure 4.23) shows complex formation at approx. 150 kDa (red square) between ITCH and hsV4N, confirmed by mass-spectrometric measurements. **C** Cross-link mass spectrometry (XL-MS) confirms a direct interaction between ITCH and hsV4N. Green bars indicate native lysine residues, whereas lysine residues involved in DSS-mediated cross-linking are additionally numbered. Black lines show cross-links between respective lysine residues. XL-MS measurements were kindly carried out by M.Sc. [REDACTED], University of Konstanz)

At time point 60 min a band of approx. 10 kDa (figure 4.25 A, red square) above the unmodified hsV4N band was observed, indicating an ubiquitination as ubiquitin has a molecular weight of 8.6 kDa. For better visualization, the time point 90 min is also shown. hsV4 ARD and hsV4 ARD-PRR showed no higher molecular weight bands and therefore no ubiquitination. For subsequent mass spectrometric identification of hsV4N ubiquitination sites, the red squared band after 60 min was cut out to rule out time-dependent unspecific ubiquitinations, as this was the earliest time point with a visible band for modified hsV4N. Four lysine residues in the intrinsically disordered region (IDR) of hsV4N were identified as ubiquitination sites: K77, K101, K130 and K136. The IDR alone includes 11 lysine residues and the whole hsV4N a total of 23 lysine residues, depicting a high lysine specificity of ITCH-mediated ubiquitination. As mentioned above, ubiquitin has a molecular weight of 8.6 kDa.

Figure 4.25: **ITCH ubiquitinates hsV4N directly.** **A** *In vitro* ubiquitination assay shows ubiquitination of hsV4N by ITCH, indicated by the bands in red squares at time points 60 min and 90 min. The band at time point 60 min was cut out and supplied to mass spectrometric detection for ubiquitination (Johns Hopkins Mass Spectrometry and Proteomics Facility). See subsection 3.10.3 for a protocol of the assay. **B** Mass spectrometry revealed the direct ubiquitination of four lysine residues (K77, K101, K130 and K136) in the hsV4 IDR by ITCH, indicated by green bars.

Therefore, hsV4N is present in a monoubiquitinated state in this assay, where each of above mentioned lysine residues is ubiquitinated once, respectively. The detected relative abundances of respective monoubiquitinated lysine harboring peptides decrease from K101>K77>K136>K130 (see section 6.7). Monoubiquitination does not target proteins for proteosomal degradation, but rather serves as a signal for membrane trafficking and endocytosis.^{172,180,181} These findings also underline the results of Wegierski *et al.*, who determined TRPV4 to be rather multi- than polyubiquitinated.¹⁷² Furthermore it was shown that the amount of internalized TRPV4 increased in the presence of ITCH, suggesting an increased ITCH-mediated TRPV4-endocytosis via monoubiquitination.^{172,173} But why is there no HECT-hsV4N IDR interaction in the shown XL-MS data in figure 4.24 C?

Figure 4.26: **Cross-link mass spectrometry (XL-MS) measurements showing inter- and/or intramolecular interactions between ITCH molecules.** **A** Topology model of full-length human ITCH with respective inter- and/or intramolecular self-crosslinks of ITCH. Green bars indicate native lysine residues, whereas lysine residues involved in DSS-mediated cross-linking are additionally numbered. Dark arches show cross-links between respective lysine residues. XL-MS measurements were kindly carried out by M. Sc. Jasmin Jansen (Working group Stengel, University of Konstanz). **B** Crystal structure of autoinhibited mouse ITCH (mmITCH) (PDB:5XMC). For better comparison with the used human constructs in this theses, highlighted residues are indicated for mouse (mm) with the corresponding human (hs) residue below. lysine residues are indicated as light green spheres. Mouse cysteine 832 (mm C832) is shown as yellow sphere, indicating the position of the catalytic active site for ubiquitin transthiolation in the HECT domain. The structure here is lacking the C2 domain, furthermore the WW3 and 4 domains were not resolved. The only structurally resolved lysine in shown murinal structure which is involved in cross-links shown in A mouse lysine 311 (mm K311), which is the corresponding lysine for human lysine 350 (hs K350).¹⁷⁵

It is known that HECT E3 ligases like ITCH exist in an autoinhibited state.^{175,179} In this autoinhibited state, the WW2 domain and a part of the linker region connecting WW2 and WW3 (referred as WW2L) bind to a hydrophobic surface opposite to the catalytic active site of the ITCH HECT domain, therefore allosterically locking the HECT domain in an inactive state (figure 4.26 A). However, binding of the ITCH interaction partner Ndfip1 to the ITCH WW2 domain releases ITCH out of its autoinhibited state.¹⁷⁵ The XL-MS data thus could represent the initiation step of the ITCH-hsV4N interaction, where hsV4N releases ITCH out of its autoinhibitory state and ITCH would be ready to receive an ubiquitin from an E2 ligase in its HECT domain. The presence of ITCH in this autoinhibited state could not be determined via self-link (inter- or intramolecular between ITCH) XL-MS data (figure 4.26), as the WW2 domain and WW2L does not harbor any lysine residues which could have been cross-linked to lysine residues in the

HECT domain. Furthermore, neither in intermolecular cross-links between hsV4N and ITCH (figure 4.24 C) nor in self-linked cross-links between or within ITCH (see 4.26 B) any HECT lysine participated in cross-linking. This could be due to the location of most HECT lysine residues, as they are buried in the N- and C-lobe of the HECT domain and therefore are unreachable for DSS for cross-linking (figure 4.26 B). Ubiquitin binding itself leads to dramatic conformational changes in the HECT domain. HECT domains consists of a so-called N- and C-lobe, with the C-lobe harboring the catalytically active site. These lobes change their overall orientation from a "closed" T-shape to an "open" L-shape upon ubiquitin binding, enabled via a flexible hinge region between the two lobes. Therefore the data suggests, that hsV4N probably releases ITCH from its autoinhibited state, enabling ubiquitin binding to the HECT domain via an E2 ligase. Due to the ubiquitin-binding, the HECT domain changes from a "closed" T-shape to an "open" L-shape, enabling an interaction of the hsV4N IDR with the HECT domain for IDR ubiquitination.¹⁸²

Interestingly, two of the ubiquitinated TRPV4 lysine residues are in close proximity to the proline rich region (PRR, K136) and the phosphoinositide-binding domain (PBD, K130) of hsV4N, two important regulatory sites in TRPV4. These modifications could thus lead to an altered binding behavior between hsV4N and other proteins, for example, between PACSIN3 and the TRPV4 PRR. As already described in section 4.3, co-expression of PACSIN 1 and 3, respectively, with TRPV4 lead to a dampened hypoosmolarity induced TRPV4-mediated Ca^{2+} -influx in HEK293T cells (figure 4.16). Furthermore, it was shown that the presence of PACSIN3 increases the plasma membrane amount of TRPV4 by probably inhibiting endocytosis, whereas ITCH decreases the TRPV4 amount in the plasma membrane via endocytosis.^{70,172} Here, two different regulating mechanisms lead to a decreased basal TRPV4 activity. The ubiquitination close to the TRPV4 PRR thus could therefore be a regulating switch between these two mechanisms: whereas PACSIN3 could provide a transient and fast TRPV4 desensitization, ITCH could disrupt this interaction via the K130 and K136 monoubiquitinations, therefore sterically hindering the PACSIN3 SH3 domain to interact with the TRPV4 PRR. This then could lead to a TRPV4 endocytosis, serving a TRPV4 "inactivation" for a longer time range.¹⁷² Furthermore, the monoubiquitination of K136 next to the PBD could lead to an impaired TRPV4-PIP₂ interaction, resulting in an altered TRPV4 regulation. Opposite consequences for the TRPV4 activity were shown upon PIP₂ binding, pointing out the need for further investigations of the consequences of TRPV4-lipid interactions.^{39,183,184}

Goretzki *et al.* showed via elaborate and comprehensive biophysical studies a structural and dynamic coupling between the TRPV4 IDR and ARD.²³ Consequently, comparably large post-

translational modifications (PTMs) in the TRPV4 IDR could thus lead to modified interactions with the TRPV4 ARD with impacts on ARD-mediated PPIs, for example. The results shown here therefore contribute to a further understanding of the PPI between hsV4N and ITCH.

4.6 TRPV4 and the actin cytoskeleton - connecting scientific disciplines

In preceding MS studies of the hsV4N interactome, conducted in the authors master thesis, a possible Ca^{2+} -dependent interaction between smooth muscle α -actin and hsV4N was observed, where α -actin amounts were higher in the samples with Ca^{2+} -supplementation.⁷⁶ This findings were especially intriguing, as TRPV4 is known to influence the microtubule and actin cytoskeleton, with consequences for cell stiffness, migratory behavior and morphogenesis.¹⁸⁵⁻¹⁸⁷ Goswami *et al.* showed a direct interaction between the TRPV4 C-terminus and actin in co-sedimentation assays, but left out hsV4N in these studies due to expression problems. Therefore, Goswami *et al.* argue that hsV4N could also play an important regulatory role in the shown colocalization between TRPV4-GFP and F-actin in transiently transfected F11 cells.¹⁸⁵ This possible cytoskeletal mediating role of hsV4N is underlined by the direct interaction between hsV4 ARD and the small GTPase RhoA shown in this thesis (section 4.4). RhoA is a prominent cytoskeleton regulator, playing a key role in stress fiber formation and actin polymerization.^{166,167,169} As a starting point to elucidate the role of hsV4N in actin regulation, the potential Ca^{2+} -dependent colocalization between the actin cytoskeleton and TRPV4 was investigated with fluorescence microscopy. HEK293 cells stably expressing human TRPV4-cGFP were treated either with 200 nM HC067 (TRPV4 antagonist) for 15 min at 37 °C, 30 nM GSK-101 for 1 min at 37 °C or left at 37 °C for 15 min without any supplementation. F-actin was visualized by subsequent phalloidin-TRITC staining (figure 4.27, for full immunostaining procedure see section 3.3). Although plenty of colocalization programs are available, either as ImageJ plugins or as commercial softwares, the algorithms and parameters of these programs are poorly described.¹⁸⁸ Furthermore, most of the programs do not provide automated image analysis, making statistical evaluations of colocalization quantification tedious and time-consuming. To circumvent the usage of "black box" programs and to provide large-scale image analysis, the theoretical chemist B. Sc. ██████████ joined this project to contribute an in-house software for colocalization studies: ELSEXY, short for Efficient Large Scale Evaluation of cross(X)-correlation Yields. Figure 4.27 shows representative fluorescence images of stably transfected HEK293 cells expressing hsTRPV4-cGFP after various treatments.

Figure 4.27: **Fluorescence microscopy images reveal stress fiber formation upon TRPV4 activation in stably transfected HEK293 cells.** Stress fiber formation was especially pronounced upon treatment with 30 nM GSK-101 for 1 min at 37 °C, with clearly visible dorsal and ventral stress fibers as well as transverse arcs, whereas only temperature activation of TRPV4 at 37 °C lead to a milder phenotype with some ventral stress fibers visible. Treatment with 200 nM of the TRPV4 antagonist HC-067 for 15 min at 37 °C showed no stress fiber development. F-actin was visualized via phalloidin-TRITC staining (see section 3.3). Scale bar = 10 µm. Images were taken with a Zeiss Axio Observer Z1 inverted widefield microscope.

Upon chemical compound activation with the potent TRPV4 activator GSK1016790A (GSK-101), cells showed explicit stress fiber formation, hinting towards a hsV4N involvement in cellular actin reassembly, as hsV4 ARD was shown to directly interact with inactive GDP-bound RhoA, the key regulator of stress fibers in cells (see section 4.4).^{166,167,169} TRPV4 activation activates RhoA, leading to a loss-of-interaction between TRPV4 and RhoA.⁶⁹ Activated, GTP-bound RhoA then mediates stress fiber formation by downstream interactors like ROCK and mDia1.¹⁶⁶ The mild stress fiber phenotype of cells after TRPV4 temperature activation hints towards a Ca^{2+} -

concentration dependency of stress fiber formation, as more physiological stimuli lead to lower amount of Ca^{2+} -influx compared to GSK-101 treatment (see also section 4.3, figure 4.16). To determine if TRPV4-mediated Ca^{2+} influx leads to an increased TRPV4-actin colocalization, fluorescence images were subjected to ELSEXY.

Shortly described, after hot-pixel and non-uniform background correction, ELSEXY calculates the Pearson Colocalization Coefficient (PCC) r of subjected fluorescence images (figure 6.8). The PCC is a measure for the linear dependency of two measured values. To obtain the PCC of the here obtained images, the measured values here are the fluorescence intensities of a pair of corresponding pixels in two fluorescence microscopy images (I_A and I_B , see equation 4.3).¹⁸⁹

$$r_{A,B} = \frac{\overline{I_A \times I_B} - \overline{I_A} \times \overline{I_B}}{\sqrt{(\overline{I_A^2} - \overline{I_A}^2) \times (\overline{I_B^2} - \overline{I_B}^2)}} \quad (4.3)$$

Due to this linear dependency, the PCC not always perfectly describes the probable colocalization in two images. Additionally, so-called M-values can improve the colocalization quantification, by calculating the fraction of colocalized intensities. This is conducted by defining thresholds for intensities. Pixel intensities above the defined thresholds in respective images

Figure 4.28: **Calculated M-values of GFP (TRPV4-cGFP) and TRITC (F-actin stained with Phalloidin-TRITC) images show decreased TRPV4 and F-actin colocalization upon TRPV4-mediated Ca^{2+} -influx in HEK293 cells.** For description of M-values see equation 4.4 and corresponding text. Box plot whiskers indicate values inside 1.5-fold interquartile range, green diamonds the arithmetic mean. Notches show 95 % confidence interval of mode. Outliers are shown as circles. $n_{\text{GSK-101}}=18$, $n_{\text{HC-067}}=28$, $n_{\text{Temp}}=33$.

are considered as colocalized. These thresholds (T_A , T_B) result from a limit intensity (I_{lim}) dependent evaluation of the PCC for pixels which are smaller than I_{lim} . M-values thereby depend on the PCC r , as the thresholds depend on each other, shown in equation 4.4.¹⁸⁹

$$M_A = \frac{\sum_{I_A > T_A \wedge I_B > T_B} I_A}{\sum I_A} \quad (4.4)$$

with $I_B = m \cdot I_A + b$.

Statistical evaluation of the colocalization between hsTRPV4-cGFP and F-actin via phalloidin-TRITC with ELSEXY showed a decreased colocalization upon TRPV4-mediated Ca^{2+} -influx (figure 4.28 and also see figures 6.9 for negative controls). These results seem to oppose the above mentioned increased actin-levels detected in hsV4N MS samples upon Ca^{2+} -supplementation.⁷⁶ One possible explanation could serve the sample preparation for subsequent MS experiments conducted by Diehl *et al.*, which differ from the protocol conducted in this work (section 3.8). Whereas in the present work a digitonin solution was used to release cytosolic proteins into the supernatant of dish-cultured HEK293 cells, the previous protocol included whole-cell lysis of HEK293 cells with a CHAPS-containing buffer. It was shown that detergents like CHAPS lead to actin depolymerization from F-actin to G-actin, therefore hinting towards the possibility that G-actin binds in a Ca^{2+} -dependent manner to hsV4N.¹⁹⁰ This hypothesis is underlined by the results of Becker *et al.* who showed that the TRPV4 C-terminus is also capable of binding G-actin in co-sedimentation assays.¹⁸⁵ The possible interaction between G-actin and hsV4N could represent a regulatory loop between TRPV4, RhoA and F-actin. TRPV4 activation leads to a reduced binding of RhoA to hsV4 ARD and activation of RhoA via GTP binding.⁶⁹ RhoA activation leads ultimately to stress fiber formation, while G-actin possibly now interacts with hsV4N. In the course of this work it was tried to clone a TRPV4 construct lacking the C-terminus to determine if only hsV4N is responsible for stress fiber formation via RhoA, but until to this date, the cloning was not successful. However, above mentioned experimental set-ups should be conducted to get a more detailed view on the hsV4N-actin interaction. Overall it could be shown that different TRPV4 activators lead to Ca^{2+} concentration dependent stress fiber formation in stably TRPV4-cGFP transfected HEK293 cells. Furthermore, the in house software ELSEXY generated preliminary Ca^{2+} -dependent colocalization data between TRPV4-cGFP and F-actin. However, ELSEXY is still in the refinement process and will give raise to a comprehensive, high-throughput colocalization studies in the future.

5 Conclusion & Outlook

Meeting at the hot-spot of disease causing TRPV4 mutations - the TRPV4 ARD and its interaction partners DDX3X and RhoA

Inada *et al.* proposed altered tissue-specific protein-protein interactions (PPIs) as a reason for the disease pathology and tissue specificity of respective TRPV4 mutations.²⁷ First results in this thesis underline before mentioned hypothesis by showing both, increased and abolished PPIs between TRPV4 harboring neuropathy-causing mutations and several cytosolic proteins. CMT2C-causing TRPV4 R232C showed increased interaction with DDX3X compared to TRPV4 wt *in vitro* and *in cellulo*, leading to decreased dxRNA-stimulated ATP-hydrolysis of DDX3X upon this interaction *in vitro* (see sections 4.1 and 4.2). This altered PPI is particularly interesting, as mutations leading to ATP-hydrolysis deficiency in DDX3X are connected to the emergence of medulloblastoma, a rapidly growing and metastasizing form of infant cerebellum tumor, and can be the cause of so-called X-linked intellectual development disorder Snijder Broks type (MRXSSB, OMIM: 300958). MRXSSB patients show a spectrum of neuropathological symptoms, but the most shared among patients are muscle hypotonia, movement disorders and aberrant intellectual development.^{139,191–195} These symptoms, especially the intellectual disability, hint towards a pivotal role of DDX3X in neuronal fetal development of the central nervous system (CNS). DDX3X mutations were shown to affect CNS neurogenesis during fetal development of the cerebral cortex. Additionally, it was shown that DDX3X plays a role in the induction of the neuronal crest during fetal development, the progenitor structure from which the peripheral nervous systems (PNS) develops from.¹⁹⁶ TRPV4-associated neuropathies affect the PNS, underlining the possible key role of the TRPV4-DDX3X interaction in PNS development and maintenance and ultimately pathological consequences due to a TRPV4 mutation induced aberrant TRPV4-DDX3X PPI, probably leading to stress granule (SG) hyperassembly in the PNS.^{31,137,197}

Pharmacological inhibition of ATP-hydrolysis or RNA-helicase activity in DDX3X via the small

molecules RK-33 or D16, respectively, showed diminished SG assembly upon arsenite induced oxidative stress in UO2S cells. Already formed SGs upon stress treatment showed no altered disassembly behavior upon RK-33 or D16 treatment, respectively.¹¹⁷ Especially regarding the ATP hydrolysis inhibition, these findings seem to contradict the results of Valentin-Vega *et al.* and in this thesis, indicating that impaired DDX3X ATP hydrolysis, either due to DDX3X mutations or altered PPIs, spur SG assembly.¹¹⁹ Yang *et al.* confirmed direct binding of RK-33 to recombinant DDX3X (aa 1-508) with isothermal calorimetry (ITC) and proposed an impaired RK-33 interaction via the active site of ATP hydrolysis due to the depletion of RK-33 binding to DDX3X K230E in sedimentation velocity assays. This mutation resides within the DDX3X Walker A motif, which is essential for DDX3X's ability to hydrolyze ATP.¹⁹⁸ However, the exact binding mode of RK-33 to DDX3X still remains elusive and therefore the overall possible structural consequences within DDX3X upon RK-33 binding. Thus, disease-causing mutations which lead to impaired ATP hydrolysis in DDX3X still could be the cause of altered PPIs and subsequent SG hyperassemblies, while pharmacological ATP hydrolysis inhibition influences DDX3X in such a manner, that pathological SG-inducing PPIs are also impaired.

To shed more light in the consequences between the here shown elevated TRPV4 R232C-DDX3X PPI, a multi-pronged approach should be performed. On one hand, NMR chemical shift perturbation assays, corresponding to the experiments in section 4.4 with hsV4 ARD and ¹⁵N-labeled RhoA, should be conducted to gain detailed insights in the direct interaction between DDX3X and hsV4 ARD and hsV4 ARD R232C, respectively. Furthermore, the influence of RK-33 on possible structural changes in DDX3X could be also investigated via NMR and compared to before mentioned NMR perturbation assays with hsV4 ARD and hsV4 ARD R232C to reveal possible difference in ATP hydrolysis inhibition via a PPI or a pharmacological inhibition. Additional *in vitro* experiments should include further ATPase assays with ARDs of other TRP channels or even other protein superfamilies to distinguish if this interaction exclusively accounts for hsV4 ARD or also other ARDs. Furthermore, functional studies of DDX3X interaction for TRPV4 should be conducted *in cellulo* via Ca²⁺-influx assays as shown in 4.3. To underline the hypothesis of SG hyperassembly due to aberrant TRPV4 R232C-DDX3X interaction, *in cellulo* experiments with transfected cells should be conducted to investigate a TRPV4 (R232C)-mediated influence upon stress granule formation with DDX3X participation via immunofluorescence staining and subsequent microscopy, for example.

Additionally, the binary TRPV4 PPIs shown in this thesis should be expanded into ternary and even quaternary PPI investigations. One starting point could be the possible ternary PPI between TRPV4, DDX3X and RhoA. For both proteins, a direct interaction with hsV4 ARD was

shown in this thesis. Furthermore it was shown that GSK-101 activation of TRPV4 wt *in cellulo* leads to a decreased PPI between TRPV4 and RhoA or DDX3X, respectively, shown by co-IPs.^{69,136} Furthermore, Phung *et al.* indicated a possible DDX3X-RhoA interplay by showing elevated levels of GTP-bound (active) RhoA in human liver cancer cell lines (HT-144 and A2058) upon DDX3X siRNA treatment, lowering but not depleting DDX3X levels in respective cell lines.¹⁹⁹ In the course of this thesis, upon the presence of a neuropathy-causing mutation, DDX3X showed an increased TRPV4 PPI, whereas RhoA showed a decreased TRPV4 PPI. It should be noted that two different neuropathy-causing mutations were used (TRPV4 R232C with DDX3X and TRPV4 R269C with RhoA). Both mutations should be investigated in the context of the ternary TRPV4-DDX3X-RhoA interaction.

Disorder matters - PPIs of the TRPV4 N-terminus underlines the pivotal role of the intrinsically disordered region

Another possible ternary PPI which could be relevant in the context of neuropathy-causing TRPV4 mutations includes TRPV4, PACSIN1 and ITCH. In this thesis it was shown that ITCH directly interacts with only the full TRPV4 N-terminus (hsV4N), but not with the TRPV4 ankyrin repeat domain (hsV4 ARD) or hsV4 ARD with the preceding proline rich region (hsV4 ARD-PRR). Furthermore it was shown, that ITCH ubiquitinates four distinct lysines in the intrinsically disordered region (IDR) of hsV4N (K77, K101, K130 and K136, see section 4.5). This is particularly interesting, as such post-translational modifications (PTMs) could interfere with possible TRPV4 PPIs. With regard of the known interaction of PACSIN SH3 domains with the TRPV4 PRR (aa 136-144), ubiquitination of lysines K130 and K136 are especially interesting with regard to possible disrupted PACSIN1/3 interactions with the TRPV4 PRR due to steric hindrance after ubiquitination of respective lysine. But also, interaction of PACSIN1/3 could prevent TRPV4 IDR ubiquitination, resulting in two different regulating mechanism leading to a decreased basal TRPV4 activity (see section 4.5). Desrochers *et al.* furthermore showed that the PACSIN1 SH3 domain interacts with the ITCH PRR located between the C2 and WW1 domain (aa 252 - 267). With the shown loss-of-interaction between PACSIN1 and TRPV4 harboring the neuropathy-causing R269C mutation with vanished TRPV4-mediated Ca²⁺-influx dampening by PACSIN1 as a consequence *in cellulo* (see section 4.3), this loss-of-interaction could also lead to an increased interaction between PACSIN1 and ITCH in neurons. The physiological consequences of this interaction still remain elusive, but one scenario could be an impaired interaction of ITCH with other proteins - TRPV4 for example. Due to the location of the ITCH PRR between two other

important regulatory domains, namely the ITCH C2 domain and the ITCH WW1 domain, interaction with PACSIN1 could therefore impair possible interactions of at least these two domains, hypothetically impairing plasma membrane localization via the ITCH C2 domain and other PPIs of the ITCH WW1 domain, if not also of the other WW domains regarding the compact structure of ITCH in its autoinhibited state (shown in figure 4.26 B). As ITCH is known to mediate TRPV4 endocytosis, a loss of interaction between PACSIN1 and TRPV4 R269C could therefore induce a vicious cycle where PACSIN1 and ITCH-mediated negative TRPV4 regulation are both abolished. This would lead then to elevated neurotoxic Ca^{2+} levels due to the elevated basal Ca^{2+} influx activity of this TRPV4 mutation (see also figure 4.17) in addition to the here showed lost interaction between TRPV4 R269C and RhoA with the cytoskeletal consequences (see 4.4).^{53,69}

Figure 5.1: **Tissue specificity of neuropathy-causing TRPV4 mutations occur due to aberrant tissue specific protein-protein interactions** Schematic representation of how TRPV4 neuropathy mutations lead to aberrant protein-protein interactions investigated in the course of this thesis. It was shown that RhoA and DDX3X specifically interact with the α -helical TRPV4 ankyrin repeat domain (ARD), whereas PACSIN1 is known to interact with the TRPV4 proline rich (PRR) region within the unstructured intrinsically disordered region (IDR) and ITCH requires the full TRPV4 N-terminus, with a possible interaction with the TRPV4 PRR.^{22,69} In the presence of a neuropathy-causing TRPV4 mutation the interactions with RhoA and PACSIN1 are abolished, with a possible consequence for the ITCH-TRPV4 interaction due to a putative increased PACSIN1-ITCH interaction. An increased interaction between neuropathy mutant TRPV4 and DDX3X was also shown in this thesis.

To elucidate this, co-IPs with cells transfected with TRPV4 (R269C), ITCH and PACSIN1 should be conducted to investigate the proposed binding competition between ITCH and PACSIN1 to TRPV4. After getting details of the interaction between ITCH and TRPV4, either with NMR studies including the ITCH WW domains and a peptide including the TRPV4 PRR or via cryo-EM with full length ITCH and hsV4N, latter experiment should be complemented with the TRPV4

R269C mutation. If both before mentioned methods should not be applicable, XL-MS studies could be conducted including hsV4N R269C with ITCH and PACSIN1, respectively, to get a detailed insight into the mutation-dependent altered PPIs.

With the comprehensive interactome study shown in this thesis, future investigations should further validate the identified putative TRPV4 interactors shown in section 4.1, especially considering the proposed role of TRPV4 in cytoplasmic granule and/or stress granule formation via its cytosolic N-terminus. Co-IPs with cells transfected with (mutated) TRPV4 and other here detected prominent SG formation proteins like TIA-1 and IGF2BP2 (figure 4.6) should be conducted, as well a possible TRPV4 mediation of altered stress granule formations under stress conditions *in cellulo*.

6.2 Appendix - Purification of biotinylated TRPV4 N-terminal proteins

Figure 6.2: **Purification of unbiotinylated hsV4 ARD Avi constructs.** A SEC purifications of unbiotinylated hsV4 ARD Avi constructs. For biotinylated constructs see figure 4.1. SEC runs were either performed with a HiLoad Superdex 75 pg preparative SEC column. Inlet shows Coomassie stained 15% SDS-PAGE of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbency at 280 nm, M = marker.

6.3 Appendix - A beginning to elucidate the versatile TRPV4 interactome

Following tables contain the mass spec data of all significant identified protein interactome members of respective TRPV4 N-terminal construct. With gene ontology and manual curation, each protein was investigated upon a possible role in RNP and/or stress granules. These tables present the current data situation in April 2021 and do not claim any comprehensiveness.

Table 6.3: List of cytoplasmic RNP granule and stress granule proteins found in the hsV4N wt Avi protein interactome determined via two independent UDMS^E in this work. *p*-values (Benjamini-Hochberg corrected Student's *t*-test) were determined of the quadruplicates of each of the two UDMS^E measurements, log₂ fold change (log₂ FC) between biotinylated and non-biotinylated hsV4N Avi wt (control) of each UDMS^E measurement. Bold numbers assign *p*- and log₂ FC values to respective UDMS^E measurement. Manual data curation was performed to determine association of detected proteins with cytosolic ribonucleoprotein (RNP) and/or stress granules (see also figure 4.4). Respective literature is appended (Lit.).

UniProt ID	-log₁₀ (<i>p</i>-value) 1	log₂ FC 1	-log₁₀ (<i>p</i>-value) 2	log₂ FC 2	RNP granules	Stress granules	Lit.

Table 6.6: List of cytoplasmic hRNP granule and stress granule proteins found in the hsV4 ARD wt protein interactome in the presence of 2 mM Ca^{2+} determined via UDMS^E in this work. *p*-values (Benjamini-Hochberg corrected Student's *t*-test) were determined of the quadruplicates of each of the two UDMS^E measurements, \log_2 fold change (\log_2 FC) between biotinylated and non-biotinylated hsV4 ARD wt Avi (control) of each UDMS^E measurement. Manual data curation was performed to determine association of detected proteins with cytosolic ribonucleoprotein (RNP) and/or stress granules (see also figure 4.6 B).

Table 6.10: List of cytoplasmic hRNP granule and stress granule proteins found in the hsV4 ARD K276E protein interactome in the presence of 2 mM Ca²⁺ determined via UDMS^E in this work. *p*-values (Benjamini-Hochberg corrected Student's *t*-test) were determined of the quadruplicates of each of the two UDMS^E measurements, log₂ fold change (log₂ FC) between biotinylated and non-biotinylated hsV4 ARD wt Avi (control) of each UDMS^E measurement. Manual data curation was performed to determine association of detected proteins with cytosolic ribonucleoprotein (RNP) and/or stress granules (see also figure 4.6 C).

6.4 Appendix - The interaction between the two protean proteins TRPV4 and DDX3X

Figure 6.3: **hsV4 ARD does not influence or inhibit the assay components lactate dehydrogenase and pyruvate kinase.** As a control for the ATPase experiments shown in section 4.2, figures 4.9 and 4.13, the well-characterized *B. subtilis* ATPase BmrA was also supplemented with hsV4 ARD to rule out unspecific effects of hsV4 ARD on the lactate dehydrogenase and pyruvate kinase used in this assay. No decrease in BmrA ATPase activity was observed upon hsV4 ARD wt supplementation. Furthermore, hsV4 ARD alone did not show ATPase activity. BmrA was kindly provided by M. Sc. [REDACTED]

6.5 Appendix - An *in cellulo* study of the interaction between human TRPV4 and PACSIN1-3

Sequence alignment between rat and human TRPV4 performed with ClustalW.²

6.6 Appendix -The small GTPase RhoA interacts with the TRPV4 Ankyrin Repeat Domain

Figure 6.4: 2D ^1H - ^{15}N -NMR spectrum of ^{15}N -RhoA: Overlay of spectra of ^1H - ^{15}N RhoA 2D HSCQs of ^{15}N -RhoA on its own (grey) confirms presence of a well-folded protein in the GDP-bound state. In the presence of hsV4 ARD wt (blue), significant line broadening is observed indicative of the formation of a high molecular weight complex. RhoA backbone NMR assignments were transferred from previously published data.¹⁷⁰

Figure 6.5: 2D ^1H - ^{15}N -NMR spectrum of ^{15}N -RhoA: Overlay of spectra of ^1H - ^{15}N RhoA 2D HSCQs of ^{15}N -RhoA on its own (grey) confirms presence of a well-folded protein in the GDP-bound state. Addition of hsV4 ARD R269C (red) shows only minor effects on the RhoA spectrum. RhoA backbone NMR assignments were transferred from previously published data.¹⁷⁰

6.7 Appendix - Interaction of ITCH requires the full TRPV4 N-terminus *in vitro*

Following table contains MS data of ubiquitinated hsV4N after an *in vitro* ubiquitination assay with ITCH (see section 4.5, figure 4.25). MS experiments were carried out by the Johns Hopkins Mass Spectrometry and Proteomics Facility.

Table 6.11: MS data of ubiquitinated hsV4N after *in vitro* ubiquitination assay with ITCH (see section 4.5, figure 4.25). Ubiquitinated sequences are indicated in blue row color. # PSMs = peptide spectrum matches, total number of identified peptide sequences.

Figure 6.6: Annotated BN PAGE samples submitted for MS measurements. See tables 6.12 and 6.12 for MS data.

Tables 6.12 and 6.12 show MS data of BN PAGE complexes of ITCH and hsV4N (see section 4.5, figure 4.24). For sample annotation, see figure 6.6. MS experiments were carried out by the Johns Hopkins Mass Spectrometry and Proteomics Facility. Due to the omission of detergent in the BN PAGE procedure, protein mixtures lead to smearing and therefore also slight contaminations in bands which supposedly should only contain one protein.⁸⁵ This is also reflected in the quantitative values shown in tables 6.12 and 6.12.

Table 6.12: MS data of BN PAGE complexes of ITCH and hsV4N (see section 4.5, figure 4.24 and figure 6.6 for sample annotation). Indicated are quantitative values normalized to total MS spectra.

6.8 Appendix - TRPV4 and the actin cytoskeleton - connecting scientific disciplines

Figure 6.7: Fluorescence microscopy images show no effect of GSK-101 or HC-067 on the cytoskeleton of untransfected HEK293 cells.

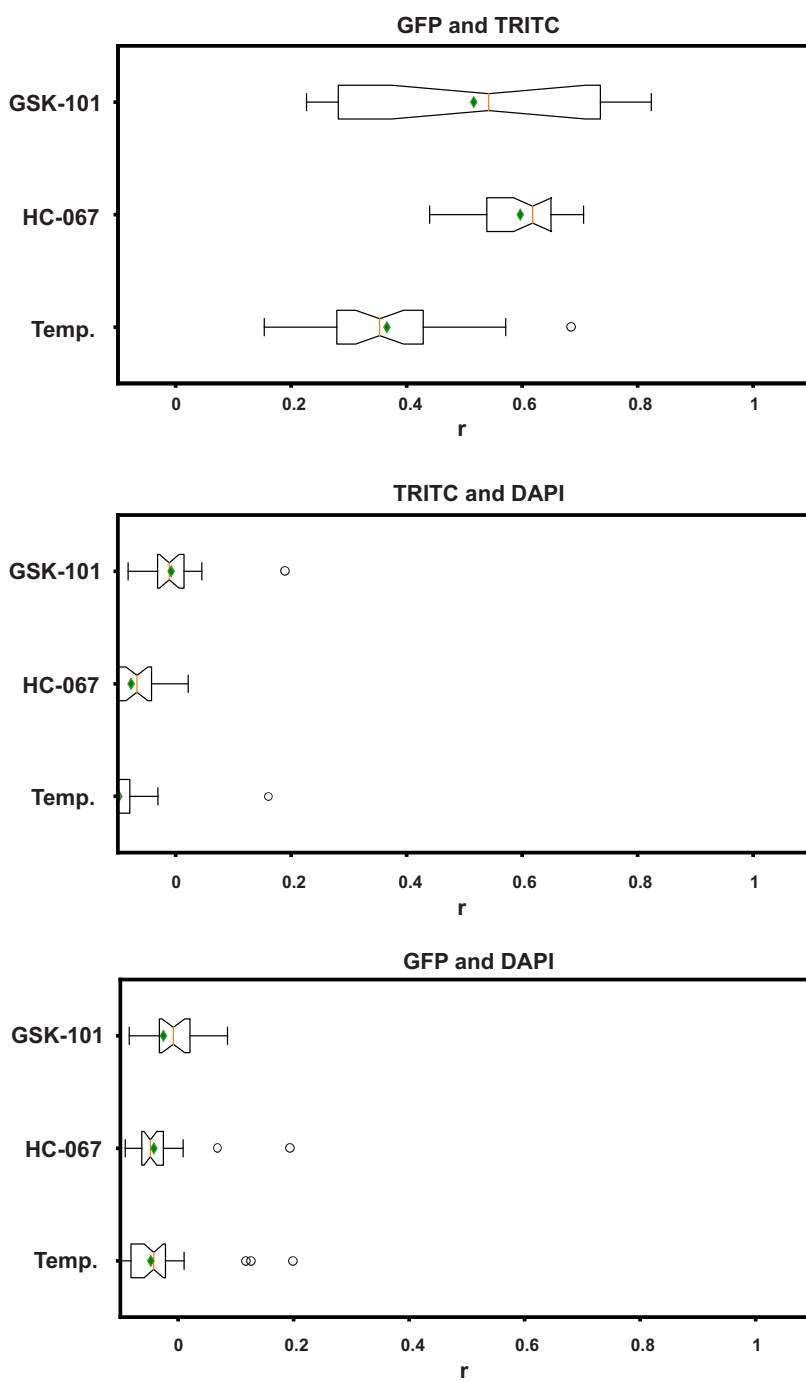

Figure 6.8: **Pearson Correlation Coefficients (PCC, r) of respective fluorescence marker pair.** GFP showed TRPV4-cGFP localization, F-actin was counter-stained with Phalloidin-TRITC and the nucleus with DAPI. Higher PCC values indicate stronger linear correlations of subjected images. See also 4.3. Box plot whiskers indicate values inside 1.5-fold interquartile range, green diamonds the arithmetic mean. Notches show 95% confidence intervall of mode. Outliers are shown as circles. $n_{GSK-101}=18$, $n_{HC-067}=28$, $n_{Temp}=33$.

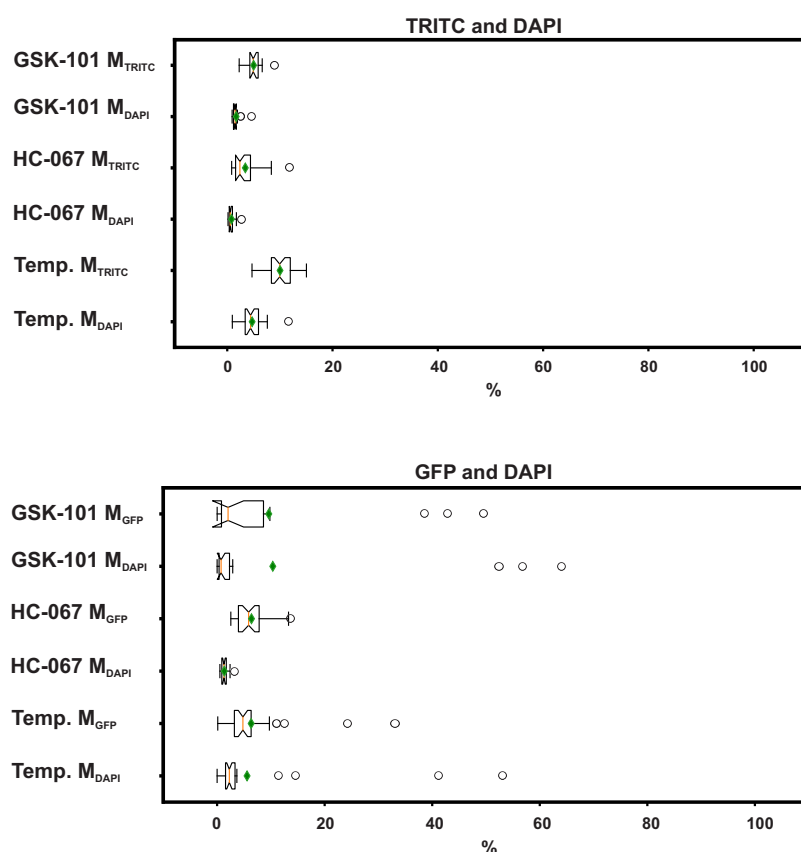

Figure 6.9: **Calculated M-values of respective fluorescence marker pairs as negative controls.** GFP showed TRPV4-cGFP localization, F-actin was counter-stained with Phalloidin-TRITC and the nucleus with DAPI. For description of M-values see equation 4.4 and corresponding text. Box plot whiskers indicate values inside 1.5-fold interquartile range, green diamonds the arithmetic mean. Notches show 95% confidence interval of mode. Outliers are shown as circles. $n_{\text{GSK-101}}=18$, $n_{\text{HC-067}}=28$, $n_{\text{Temp}}=33$.

Table 6.14: P and M-values of GFP (TRPV4-cGFP) and TRITC (F-actin stained with Phalloidon TRITC) images of stably transfected HEK293 cells upon various treatments, determined and calculated by ELSEXY (see also figures 4.28, 6.9 and 6.8). PCC = Pearson correlation coefficient r

6.9 Appendix - Establishing HEK293 cell lines stably expressing TRP channels

In the course of this work, HEK293 cells stably expressing human TRPV4-cGFP and TRPML1-cGFP, respectively, were established (see section 3.2.3 for procedure). In both cases, fluorescence microscopy images showed expected subcellular localization, as shown for human TRPV4-cGFP in figure 6.10 and human TRPML1-cGFP 6.12. Furthermore, for HEK293 hsTRPV4-cGFP cells, functionality of hsTRPV4-cGFP was confirmed via a Ca^{2+} -influx assay, in agreement with McCray *et al.*⁶⁹

Figure 6.10: **Fluorescence microscopy images of HEK293 cells stably transfected with hsTRPV4-cGFP.** Stable transfection was achieved as described in subsection 3.2.3. hsTRPV4-cGFP shows expected plasma membrane localization.

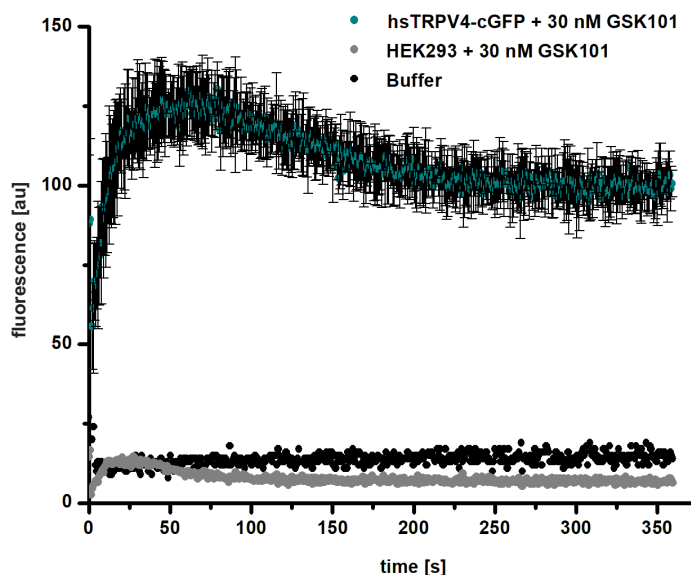

Figure 6.11: **Stably transfected HEK293 cells express functional hsTRPV4-cGFP.** Functionality of expressed hsTRPV4-cGFP upon GSK101 activation, evaluated via a Ca^{2+} -influx assay performed with the Fluo-4 Direct Calcium Assay (see table 2.18). x-axis = time in seconds, y-axis: fluorescence in arbitrary units. Averages represent $n = 3$, error bars indicate SD.

Figure 6.12: **Fluorescence microscopy images of HEK293 cells stably transfected with hsTRPML1-cGFP.** Stable transfection was achieved as described in subsection 3.2.3. hsTRPML1-cGFP shows expected localization in vesicular structures (indicated by white arrow heads), which are most likely lysosomes.²²⁹

6.10 Appendix - Purification of ITCH WW domains

ITCH contains four WW domains (WW1-4), which could be possible interaction domains for the TRPV4 PRR.²³⁰ To probe possible PPIs between the ITCH WW domains and TRPV4 PRR in detail recombinant expression of all four single WW domains and the tandem domains WW1+2 and 3+4 was established (see section 3.7.8). Furthermore, first purifications and characterizations of the WW1+2 and 2+3 tandem domains were carried out (figure 6.13).

Figure 6.13: **Purification of recombinant human ITCH WW domains** **A** SEC purification of human ITCH WW1+2 and WW3+4 tandem domains. SEC runs were performed with a HiLoad Superdex 75 pg preparative SEC column. Inlet shows Coomassie stained 15% SDS-PAGE of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbency at 280 nm, M = marker. **B** Far UV CD spectrum of human WW1+2 and WW3+4 tandem domains. Spectra were measured at 293 K and proteins were used at 1 μ M concentration in either SEC Buffer with a final NaCl concentration of 20 mM NaCl. Inlet shows secondary structure prediction performed with CAPITO.⁹³ The predicted α -helix/ β -sheet/random coil content of the purified proteins is for ITCH WW1+2 tandem domain 10%/32%/58% and ITCH WW3+4 tandem domain 5%/37%/59%. x-axis: mean residue ellipticity ($[\Theta]_{mrw,\lambda}$) in 10^{-3} deg $\text{cm}^2 \text{dmol}^{-1}$, y-axis: wavelength λ in nm.

6.11 Appendix - Purification of YAP1 WW domains

YAP1 contains two WW domains, which could be possible interaction domains for the TRPV4 PRR.²³⁰ To probe possible PPIs between the YAP1 WW domains and TRPV4 PRR in detail, recombinant expression of the YAP-1 WW1 domain and YAP1 WW1+2 tandem domain was established (see section 3.7.9). Furthermore, first purifications and characterizations of the YAP1 WW1 and WW1+2 tandem domain were carried out (figure 6.14). Expression conditions and subsequent purification of the YAP1 WW2 domain have still to be optimized.

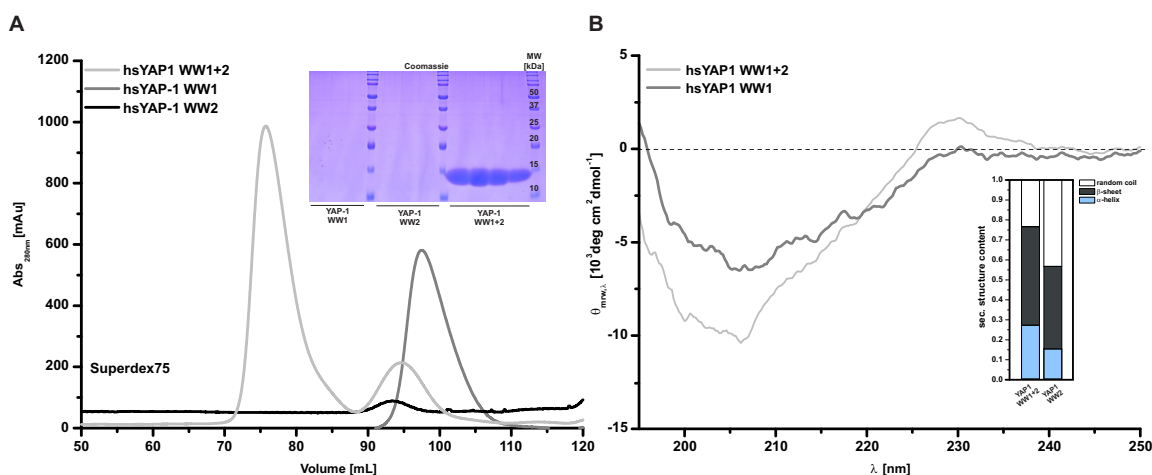

Figure 6.14: **Purification of recombinant human YAP1 WW domains** **A** SEC purification of human YAP1 WW1+2 tandem and YAP1 WW1 domain. SEC runs were performed with a HiLoad Superdex 75 pg preparative SEC column. Inlet shows Coomassie stained 15% SDS-PAGE of collected and concentrated fractions after SEC. x-axis: eluted volume in mL, y-axis: absorbency at 280 nm, M = marker. **B** Far UV CD spectrum of human YAP1 WW1+2 tandem and YAP1 WW1 domain. Spectra were measured at 293 K and proteins were used at 1 μ M concentration in either SEC Buffer with a final NaCl concentration of 20 mM NaCl. Inlet shows secondary structure prediction performed with CAPITO.⁹³ The predicted α -helix/ β -sheet/random coil content of the purified proteins is for YAP WW1+2 tandem domain 3%/50%/47% and YAP1 WW1 domain 2%/42%/56%. x-axis: mean residue ellipticity ($[\Theta]_{mrw,\lambda}$) in 10^{-3} deg cm² dmol⁻¹, y-axis: wavelength λ in nm.

6.12 Appendix - Amino acid and DNA sequences

7 List of Figures

1.1	Multiple alignment phylogenetic tree of the mammalian TRP channel superfamily.	17
1.2	Structures of human TRP channels	19
1.3	TRP channel PPI network extracted from the TRIP Database.	20
1.4	Distribution of TRPV4 channelopathy mutations	22
4.1	Purification of <i>in vivo</i> biotinylated and structural intact TRPV4 N-terminal constructs	85
4.2	Outline of the proteomics workflow performed in this work	88
4.3	UDMS ^E measurements revealed up to 64 probable hsV4N protein interactors.	89
4.4	Interaction map and GO Enrichment Components and Processes of hsV4N interactome proteins detected via UDMS ^E 90	
4.5	Interaction map and GO Enrichment Components and Processes of hsV4N interactome proteins detected via UDMS ^E with Ca ²⁺ sample supplementation	93
4.7	Overlap of proteins detected in respective detected in respective UDMS ^E experiments without (A) and with Ca ²⁺ sample supplementation (B)	95
4.6	Interaction map and GO Enrichment Components and Processes of hsV4 ARD wt Avi, hsV4 ARD R232C Avi and hsV4 ARD K276E Avi interactome proteins detected via UDMS ^E without and with Ca ²⁺ sample supplementation	95
4.8	Purification of recombinant TRPV4 N-terminal constructs and human DDX3X	100
4.9	hsV4 ARD, but not hsV4N, decreases the DDX3X ATPase activity	102
4.10	XL-MS confirms a direct interaction between hsV4N and DDX3X	103
4.11	hsV4 ARD interacts with dxRNA-bound DDX3X	104
4.12	dsRNA binding changes the tryptophan environment in DDX3X dramatically.	106
4.13	Inhibition of DDX3X ATPase activity is enhanced in the presence of neuropathy-causing TRPV4 R232C mutation.	107
4.14	Co-Immunoprecipitations of various full-length human TRPV4-GFP constructs and DDX3X-V5 in HEK293 cells show an increased DDX3X-V5 pulldown with the neuropathy-causing TRPV4-R232C mutation	108
4.15	Immunofluorescence images of HEK293T cells co-transfected with TRPV4-GFP (green) and DDX3X-V5 (magenta) reveal an cytosolic DDX3X densification, especially in the presence of TRPV4-R232C-GFP.	109
4.16	Human PACSIN1 and 3, but not PACSIN2, dampen human TRPV4-mediated Ca ²⁺ -influx in transiently transfected HEK293T cells upon hypotonicity	113
4.17	Human PACSIN1 does not dampen human TRPV4-mediated Ca ²⁺ -influx in HEK293T cells transiently transfected with TRPV4 R269C upon hypotonicity.	115
4.18	PACSIN chimeras hint towards regulation modes between PACSIN1 and PACSIN3 on TRPV4-mediated Ca-influx in HEK293T cells	116
4.19	Purification of hsV4 ARD wt and ¹⁵ N-RhoA ¹⁵ N-RhoA	120
4.20	NMR experiments revealed an decreased PPI between ¹⁵ N-RhoA and the neuropathy-causing mutation R269C in hsV4 ARD.	122
4.21	Relative signal intensity changes of RhoA in the presence of unlabeled hsV4 ARD wt and R269C, respectively.	123
4.22	Interaction sites of hsV4 ARD with ¹⁵ N-RhoA	124
4.23	Purification of recombinant TRPV4 N-terminal constructs and human ITCH	126
4.24	ITCH and hsV4N are direct interaction partners	129
4.25	<i>In vitro</i> ubiquitination assay shows ubiquitination of hsV4N by ITCH	130

Chapter 7. List of Figures

4.26 Cross-link mass spectrometry (XL-MS) measurements showing inter- and/or intramolecular interactions between ITCH molecules	131
4.27 Fluorescence microscopy images reveal stress fiber formation upon TRPV4 activation in stably transfected HEK293 cells.	134
4.28 ELSEXY GFP TRITC	135
5.1 Tissue specificity of neuropathy-causing TRPV4 mutations occur due to aberrant tissue specific protein-protein interactions	141
6.1 TRP channel PPI network extracted from the TRIP Database.	143
6.2 Purification of unbiotinylated hsV4 ARD Avi constructs	152
6.3 hsV4 ARD does not influence or inhibit the assay components lactate dehydrogenase and pyruvate kinase	177
6.4 Overlay of spectra of ^1H - ^{15}N RhoA 2D HSCQs of ^{15}N -RhoA on its own and with hsV4 ARD wt	183
6.5 Overlay of spectra of ^1H - ^{15}N RhoA 2D HSCQs of ^{15}N -RhoA on its own and with hsV4 R269C	184
6.6 Annotated samples in BN PAGE, submitted to MS measurements	189
6.7 Fluorescence microscopy images show no effect of GSK-101 or HC-067 on the cytoskeleton of untransfected HEK293 cells	192
6.8 Pearson Correlation Coefficients (PCC, r) of respective fluorescence marker pair.	193
6.9 M-values	194
6.10 Fluorescence microscopy images of HEK293 cells stably transfected with hsTRPV4-cGFP	201
6.11 Stably transfected HEK293 cells express functional hsTRPV4-cGFP.	201
6.12 Fluorescence microscopy images of HEK293 cells stably transfected with hsTRPML1-cGFP	202
6.13 Purification of recombinant human ITCH WW domains	202
6.14 Purification of recombinant human YAP1 WW domains	203

8 List of Tables

2.1	Chemicals	29
2.2	General buffer and solutions	31
2.3	Buffer and solutions for purification of hsV4N, hsV4N Δ 122 and hsV4N Δ 132 constructs. hsV4N Δ 132 is also referred to as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR.	34
2.4	Buffer and solutions for purification of hsRhoA	35
2.5	Buffer and solutions for purification of hsDDX3X_aa122-582 (DDX3X)	36
2.6	Buffer and solutions for purification of hsITCH	37
2.7	Buffer and solutions for purification of hsITCH WW domain constructs	38
2.8	Buffer and solutions for purification of TRPC 3, 4 and 6 ARDs	39
2.9	Buffer and solutions for purification of hsYAP-WW domains	40
2.10	Enzymes	41
2.11	Antibodies	42
2.12	Oligonucleotides for Quickchange PCR	43
2.12	Oligonucleotides for Quickchange PCR	44
2.13	Oligonucleotides for Gibbson Assembly	44
2.13	Oligonucleotides for Gibbson Assembly	45
2.14	Sequencing oligonucleotides	45
2.15	Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.	47
2.15	Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.	48
2.15	Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.	49
2.15	Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.	50
2.15	Expression plasmids generated and used in the course of this work. hsV4N Δ 132 is also referred as hsV4 ARD, hsV4N Δ 122 as hsV4 ARD-PRR. The nomenclature of the plasmids refers to the employed nomenclature at the Hellmich workgroup.	51
2.16	Characteristics of proteins and peptides used in this thesis.	52
2.17	Characteristics of proteins and peptides used in this thesis.	53
2.18	Kits	54
2.19	Media and supplements for cell culture	55
2.20	Cells	55
2.20	Cells	56
2.21	Laboratory equipment	56

Chapter 8. List of Tables

2.22 Software	57
3.1 DpnI digestion reaction mixture	60
3.2 Reaction mixtures for Gibson Assembly	60
3.3 Composition of the stacking and separation gel for SDS-PAGE	61
3.3 Composition of the stacking and separation gel for SDS-PAGE	62
3.4 Used primary antibody solutions and blocking solutions	62
3.5 Used secondary antibody solutions	63
3.6 Used SEC columns, manufactured by GE Healthcare	64
3.7 Used plasmid DNA amounts for transfections of HEK293T cells with Lipofectamine®LTX	65
3.8 Used plasmid amounts for stable transfections of HEK293 cells with Lipofectamine®LTX	67
3.9 Antibodies used for cell immunostainings	68
3.10 Expression conditions of human N-terminal TRPV4 (hsV4N) constructs	70
3.11 Expression conditions of human RhoA	73
3.12 Expression conditions of hsDDX3X	73
3.13 Expression conditions of human ITCH	74
3.14 Expression conditions of human ITCH WW domains	75
3.15 Expression conditions of human YAP WW domains	76
3.16 Sample composition for the <i>in vitro</i> -ATPase assay	80
3.17 Sample composition for the <i>in vitro</i> -Ubiquitinylation assay	81
4.1 Sample overview of hsV4N interactome pulldowns with HEK293 cytosolic protein extracts	87
6.1 List of human TRP channel protein interactors deposited in the TRIP database	144
6.2 List of known TRPV4 interactors deposited in the TRIP database	146
6.3 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4N protein interactome via UDMS ^E in this work	153
6.4 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4N protein interactome in the presence of 2 mM Ca ²⁺ via UDMS ^E in this work	155
6.5 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD wt protein interactome determined via UDMS ^E in this work	158
6.6 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD wt protein interactome in the presence of 2 mM Ca ²⁺ determined via UDMS ^E in this work	160
6.7 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD R232C protein interactome determined via UDMS ^E in this work	165
6.8 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD R232C protein interactome in the presence of 2 mM Ca ²⁺ determined via UDMS ^E in this work	166
6.9 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD K276E protein interactome determined via UDMS ^E in this work	168
6.10 List of cytoplasmic RNP granule and stress granule proteins found in the hsV4 ARD K276E protein interactome in the presence of 2 mM Ca ²⁺ determined via UDMS ^E in this work	173
6.11 MS data of ubiquitinated hsV4N after <i>in vitro</i> ubiquitination assay with ITCH	185
6.12 MS data of BN PAGE complexes of ITCH and hsV4N	190
6.14 P and M-values of GFP (TRPV4-cGFP) and TRITC (F-actin stained with Phalloidon TRITC) images of stably transfected HEK293 cells upon various treatments, determined and calculated by ELSEXY (see also figures 4.28, 6.9 and 6.8). PCC = Pearson correlation coefficient <i>r</i>	194
6.15 P and M-values of TRITC (F-actin stained with Phalloidon TRITC) and DAPI (Nucleus) images of stably transfected HEK293 cells upon various treatments, determined and calculated by ELSEXY (see also figures 4.28, 6.9 and 6.8). PCC = Pearson correlation coefficient <i>r</i>	196

6.16 P and M-values of GFP (TRPV4-cGFP) and DAPI (Nucleus) images of stably transfected HEK293 cells upon various treatments, determined and calculated by ELSEXY (see also figures 4.28, 6.9 and 6.8). PCC = Pearson correlation coefficient r 198

Curriculum Vitae

Education and Research Experience

- Jan 2019 –
Jun 2019 Visiting researcher at the research group of Prof. ██████████, Johns Hopkins University, USA (Fulbright Fellowship).
“The impact of selected TRPV4 interactors upon TRPV4 mediated Ca²⁺-influx activity”
Live Ca²⁺-influx imaging in cellulo. Immunostaining and subsequent confocal microscopy. Mouse studies on peripheral neuropathies.
- Since Apr
2017 PhD candidate in chemistry (TransMED as well as Sybille Kalkhof Rose-Fellowship), Johannes Gutenberg-University (JGU) Mainz
“Elucidating molecular details in the interactome of the human ion channel TRPV4”
Investigation of direct protein-protein interactions (PPI) via UDMS^E, NMR and analytical FPLC. Indirect PPI studies via co-IPs and microscopical co-localization studies. Developing an in-house software for microscopical co-localization analysis.
- Jun 2016 –
Apr 2017 Master-Thesis, “Investigating the interactome of the TRPV4 N-terminus”, JGU Mainz
Recombinant expression of human proteins in E. coli, P. pastoris and HEK293T cells. Purification via several chromatographic methods, including preparative FPLC. Confirming structural protein integrity via CD spectroscopy and 2D-NMR.
- Apr 2015 –
Jun 2015 Research internship, “AOM-induced colorectal carcinogenesis in PARP-1 k.o. mice”, JGU Mainz
Inducing colorectal cancer in PARP-1 k.o. mice. Evaluation of carcinogenesis in vivo via colonoscopy. Immunohistostaining of colorectal tissues and subsequent confocal microscopy. ELISAs for TNF α level determination.
- Oct 2014 –
Apr 2017 Studies in Biomedical Chemistry (M.Sc.), JGU Mainz
Elective subjects: Pharmacology, Oncology
- Apr 2014 –
Mar 2016 Student staff member at the IMG Innovations-Management GmbH
Novelty assessment of inventions with focus on industrial property rights in life science and chemistry. Composition of technological summaries of approved patents in English and German. Acquisition of technology licensees.
- Apr 2014 –
Sep 2014 Bachelor-Thesis, “Influence of disulfide compounds on the tumor-suppressor protein p53”, JGU Mainz
Cell culture with colorectal cancer cell lines. ELISAs, EMSAs with subsequent Western- and Southern blotting. Recombinant expression of human proteins in Sf9 insect cells via baculoviruses
- Oct 2013 –
Apr 2014 Interdisciplinary advanced seminar “Tumor biology, oncological dia-gnostics and novel therapies”, JGU Mainz
- July 2012 Extracurricular research internship, “Expression level of CD91 in leukemic stem cells”, JGU Mainz
Cell culture with suspension cells, FACS
- Oct 2010 –
Sep 2014 Studies in Biomedical Chemistry (B.Sc.), JGU Mainz
Elective subject: Genotoxicology
- Mar 2010 Higher education entrance qualification, “Abitur”
Gymnasium Kusel

Awards

Nov 2019	Sybille Kalkhof Rose-Stiftung Fellowship
Sep 2019	Best Talk Award of a young researcher by the association <i>frei für forschung – Neue Wege in der Medizin e.V.</i> at the 6 th TransMED ScienceDay, JGU Mainz
Sep 2018	Science Award by the association <i>frei für forschung – Neue Wege in der Medizin e.V.</i> at the CRISPR Genome Editing Workshop, JGU Mainz
Aug 2018	Fulbright Fellowship
Mar 2018	Best Presentation Award at the 3 rd Interdisciplinary symposium JGU Mainz
Oct 2017	TransMED – Mainz Research School of Translational Biomedicine Fellowship

Organizing and Teaching Experience

Oct 2017+ Apr 2018	Conference conception and organization of 2 nd BioChem Symposium and 3 rd Life Science Meeting, JGU Mainz
since Apr 2017	Supervision of 9 undergraduate students during their Bachelor and Master theses in (biomedical) chemistry. Conception and lecturing of undergraduate literature seminars and practical courses in “Biochemistry 2”
Oct 2011 – Oct 2012	Undergraduate research assistant, JGU Mainz Conception, supervision and correction of exams in the subject “Allgemeine und anorganische Chemie I”.

List of publications

Supervised theses

- Jul 2020 – ██████████ – Bachelor thesis “A biochemical study of selected TRPV4
Oct 2020 interaction partners”
- Jun2018 – ██████████ Diploma thesis “Investigating the Interactome of the Human Ion Channel
Mar 2019 TRPV4 and Associated Channelopathies”
- Oct 2017 – ██████████ – Bachelor thesis “Biochemische Studien an Ankyrin Repeat
Jan 2018 Domains von TRPV-Ionenkanälen”

Conference contributions (Selection)

- Sep 2019 6th TransMed Science Day, JGU Mainz
“Towards elucidating the channelopathy interactome of the human ion channel
TRPV4” (talk)
- Sep 2018 Laureate lecture at the CRISPR Genome Editing Workshop, JGU Mainz
“Why CRISPR? A TR(i)P through the interactome world of the Transient Receptor
Potential channel 4”
- Mar 2018 3rd Interdisciplinary Symposium, JGU Mainz
“Transient receptor potential channels – Building a bridge between Aristotle and
chili” (talk)
