33 **Contribution to articles included in the dissertation**

34 **1. Title:** COX2-inhibitory and cytotoxic activities of phytoconstituents of *Matricaria*  
35 *chamomilla* L.

36 **Authorship contribution:** A.I.D. performed the experiments and analyses; B.A. performed the  
37 phytochemical analysis; I.A.K. edited the manuscript; and T.E. supervised the project and wrote  
38 the manuscript. All authors have read and agreed to the published version of the manuscript.

39 **2. Title:** Anti-Inflammatory and Cancer-Preventive Potential of Chamomile (*Matricaria*  
40 *chamomilla* L.): A Comprehensive in Silico and In Vitro Study

41  
42 **Authorship contribution:** A.I.D. performed the experiments and analyses, R.Y. assisted in  
43 conducting experiments and analysis. R.D. performed the microscale thermophoresis  
44 experiment, N.T.A. Wrote the methodology for the cell cycle and annexin-v apoptosis  
45 experiment in the material and methods section, T.H.A.H. performed the docking analysis of  
46 the protein tubulin, B.A. performed the phytochemical analysis, I.A.K. edited the manuscript,  
47 and T.E. supervised the project and wrote the manuscript. All authors have read and agreed to  
48 the published version of the manuscript.

49  
50 **3. Title:** In Silico and In Vitro Screening of 50 Curcumin Compounds as EGFR and NF- $\kappa$ B  
51 Inhibitors

52  
53 **Authorship contribution:** T.E. and B.B. designed the study. R.Y., A.D. and M.D. performed  
54 molecular docking experiments and calculations. M.E.M.S., E.O., R.Y., E.-J.S., A.D., M.D. and  
55 O.K. carried out the experiments. S.J.T. and F.S.K. synthesized the compounds. M.-E.F.H.  
56 optimized the compounds and revised the structures for molecular docking. T.E. supervised the  
57 work and provided the facilities for the study. M.E.M.S. and T.E. wrote the manuscript. All  
58 authors have read and agreed to the published version of the manuscript.

## 69 **Acknowledgment**

70 First and foremost, I would like to express my sincere gratitude to my supervisor, Prof. Dr.  
71 Efferth. I am truly grateful that he gave me the opportunity to pursue my Ph.D. within his  
72 renowned group. He allowed me to learn and grow in our field, which I am most passionate  
73 about. Namely, inflammation and cancer treatment with phytomedicines. I also grew personally  
74 during this time. I learned that in science, it is most important to never give up. It is okay to  
75 make mistakes and learn from them and working as a team gives us strength. Professor Efferth is  
76 known for his strong scientific background and outstanding academic performance, and I am  
77 lucky to be his student. I can't thank him enough for his support and immense patience.

78 My thanks goes to my collaborator Dr. Avula and Professor Khan for performing the chamomile  
79 compounds extractions and delivering it to us. Besides, my thanks go to my co-authors for their  
80 efforts and engagement in the research work. "If I have seen further, it is by standing on the  
81 shoulders of giants." Isaac Newton, Letter to Robert Hooke, 1675

82 I would like to thank Prof. Dr. Freedland, Prof. Dr. Thomas Efferth, Prof. Dr. Peter Langguth for  
83 taking part in the dissertation committee, and Dr. Rümeysa Yücer for being the secretary in the  
84 oral examination.

85 I would like to express my warmest gratitude to my father Dr. Boualem Drif, my mother Dr.  
86 Nawal Drif, my husband Maximilian Hornstein, my sister Assila, my brother Sido, my father-in-  
87 low Dr. Hornstein, and my mother-in-low Doris Hornstein. I am grateful for my family for  
88 standing with me and supporting me in sickness and health throughout this whole journey. I must  
89 thank my parents and my husband for their unconditional love and support.

90 Last but not least, I have special thanks to my friends in Germany who have always been a major  
91 source of support when things would get discouraging, Dr. Xiaohua Lu, Dr. Yücer Rümeysa,  
92 Nasim Shahhamzehei, Kaushik Iyer, Ejlal Omer, Dr. Joelle C Boulos, Dr. Min Zhou, Dr. Mona  
93 Dawood, Varol Ayşegül, Mohamed Elbadawi, and so forth.

94 Special gratitude to Latifa, Ghalia, Bota, Thomas, Amir, Melissa, Roberto, Raphaella. "There is  
95 nothing I would not do for those who are really my friends. I have no notion of loving people by  
96 halves; it is not my nature." Jane Austin, Northanger Abbey.

97 **Abstract**

98 Natural products have shown great potential due to their biological properties and their bioactive  
99 components, which demonstrate multiple mechanisms of action and lower cytotoxicity compared  
100 to conventional synthetic drugs. This dissertation focuses on the therapeutic potential of  
101 chamomile molecules (*Matricaria chamomilla* L.) and curcumin analogues (from *Curcuma*  
102 *longa* L.), as anti-inflammatory and cancer preventive agents.

103 In our investigations, an *in silico* virtual drug screening by molecular docking of 212  
104 phytochemicals from chamomile revealed potential COX2 and NF- $\kappa$ B inhibitors, including  $\beta$ -  
105 amyryn,  $\beta$ -sitosterol, myricetin, lupeol, and quercetin. The *in silico* findings were validated  
106 through microscale thermophoresis and biochemical assays. The use of the various -omics  
107 facilitate the profiling of the bioactivity of these compounds. Furthermore, the bioinformatic  
108 analysis were then further verified through cytotoxicity assays using various cancer cell lines,  
109 and flow cytometric assays. These experiments allowed to demonstrate the potential to overcome  
110 resistance mechanisms associated with established anticancer drugs. In addition to evaluate their  
111 effect on modulating the reactive oxygen species generation and mitochondrial membrane  
112 potential. Moreover, the immunofluorescence microscopy of  $\alpha$ -tubulin revealed significant  
113 correlations between the chamomile compounds myricetin, lupeol, and quercetin and vincristine,  
114 a well-established microtubule inhibitor. Notably, lupeol and quercetin induced G2/M cell cycle  
115 arrest and apoptosis. Further, western blot and RT-PCR assays were performed to highlights the  
116 involvement of the chamomile compounds in the regulation of immune response during  
117 inflammation.

118 Similarly, an extensive analysis of 50 curcumin derivatives demonstrated their binding affinity  
119 to key cancer-related target proteins, including EGFR and NF- $\kappa$ B. The study indicated that  
120 several curcumin analogues had a stronger binding affinity than curcumin itself, suggesting that  
121 their derivatization could lead to improved target specificity and enhanced efficacy as anticancer  
122 agents. This was supported by a variety of bioactivity assays, including resazurin cell viability,  
123 assessment of oxidative stress and lactate dehydrogenase assays.

124 In conclusion, our research highlights the ability of chamomile and curcumin derivatives to  
125 influence various biological processes within the cell and their therapeutic potential in treating  
126 inflammation and preventing cancer. Given the promising attributes of these natural products, it  
127 seems promising to further investigate them *in vitro* and *in vivo* studies, as well as in clinical  
128 trials.

## 129 **Zusammenfassung**

130 Naturarzneimittel haben ein großes Potenzial aufgrund ihrer biologischen Eigenschaften und  
131 bioaktiven Inhaltsstoffe, die mehrere Wirkmechanismen und eine geringere Zytotoxizität als  
132 herkömmliche synthetische Arzneimittel aufweisen. Diese Dissertation befasst sich mit dem  
133 therapeutischen Potential von Molekülen der Kamille (*Matricaria chamomilla* L.) und von  
134 Curcumin-Analoga (aus *Curcuma longa* L.) als entzündungshemmende und krebsvorbeugende  
135 Wirkstoffe.

136 In unseren Untersuchungen wurden durch ein virtuelles *in silico* Wirkstoffscreening mittels  
137 molekularen Dockings von 212 Phytochemikalien der Kamille potenzielle COX2- und NF- $\kappa$ B-  
138 Inhibitoren identifiziert, darunter  $\beta$ -Amyrin,  $\beta$ -Sitosterol, Myricetin, Lupeol und Quercetin. Die  
139 *in silico* gewonnenen Erkenntnisse wurden durch mikroskopische Thermophorese und  
140 biochemische Assays validiert. Die Anwendung verschiedener -omics ermöglicht die Erstellung  
141 von Bioaktivitätsprofilen dieser Verbindungen. Darüber hinaus wurden die bioinformatischen  
142 Analysen durch Zytotoxizitätstests mit verschiedenen Krebszelllinien und  
143 durchflusszytometrische Assays weiter verifiziert. Mit diesen Experimenten konnte das Potenzial  
144 zur Überwindung von Resistenzmechanismen gegenüber etablierten Krebsmedikamenten  
145 nachgewiesen werden. Des Weiteren wurde ihr Effekt auf die Modulation der Bildung reaktiver  
146 Sauerstoffspezies und des mitochondrialen Membranpotenzials evaluiert. Die  
147 Immunfluoreszenzmikroskopie von  $\alpha$ -Tubulin zeigte darüber hinaus signifikante Korrelationen  
148 zwischen den Kamilleninhaltsstoffen Myricetin, Lupeol, Quercetin und dem bekannten  
149 Mikrotubuli-Inhibitor Vincristin. Insbesondere Lupeol und Quercetin induzierten eine  
150 Verlangsamung des G2/M-Zellzyklus und Apoptose. Zusätzlich wurden Western Blot- und RT-  
151 PCR-Assays durchgeführt, um die Beteiligung von Kamilleninhaltsstoffen an der Regulation der  
152 Immunantwort bei Entzündungen zu untersuchen.

153 Eine umfassende Analyse von 50 Curcumin-Derivaten zeigte deren Bindungsaffinität zu  
154 wichtigen krebserlevanten Zielproteinen, darunter EGFR und NF- $\kappa$ B. Die Studie zeigte, dass  
155 mehrere Curcumin-Analoga eine höhere Bindungsaffinität aufwiesen als Curcumin selbst, was  
156 darauf hindeutet, dass ihre Derivatisierung zu einer verbesserten Zielspezifität und Wirksamkeit  
157 als Krebsmedikament führen könnte. Diese Beobachtung wurde durch eine Reihe von  
158 Bioaktivitätstests bestätigt, einschließlich Resazurin-Zellviabilität, oxidativer Stressbewertung  
159 und Laktatdehydrogenasetests.

160 Zusammenfassend unterstreichen unsere Untersuchungen die Fähigkeit von Kamille- und  
161 Curcumin-Derivaten, verschiedene biologische Prozesse in der Zelle zu beeinflussen, sowie ihr  
162 therapeutisches Potenzial bei der Behandlung von Entzündungen und der Prävention von Krebs.  
163 Angesichts der vielversprechenden Eigenschaften dieser Naturkomponenten erscheint es  
164 vielversprechend, sie in *in vitro* und *in vivo* Studien sowie in klinischen Versuchen weiter zu  
165 untersuchen.

## 194 **1. Introduction**

195 Inflammation and cancer are interconnected through complex molecular pathways, and NF- $\kappa$ B  
196 plays a major role in both these processes. In inflammation, NF- $\kappa$ B is a key activator of  
197 inflammation, orchestrating the expression of proinflammatory genes. Simultaneously, one  
198 downstream effect of this is the upregulation of cyclooxygenase-2 (COX-2), a mediator of  
199 inflammation, which, in turn, sustains NF- $\kappa$ B activation, creating a feedback loop. In cancer, this  
200 continuous expression of NF- $\kappa$ B becomes particularly consequential, especially when coupled  
201 with oncogenic pathways such as the epidermal growth factor receptor (EGFR) signaling.  
202 Together, these mechanisms lead to constitutive NF- $\kappa$ B activation, enhancing cancer cell  
203 resistance to apoptosis and supporting tumor survival. This intricate interplay between  
204 inflammation and cancer, mediated by NF- $\kappa$ B, presents both challenges and opportunities in  
205 understanding and treating inflammation and malignancies. Therefore, our research focuses on  
206 natural, compound-based treatments targeting NF- $\kappa$ B, COX<sub>2</sub>, and EGFR, specifically examining  
207 the bioactive compounds in chamomile and turmeric, both known for their anti-inflammatory  
208 properties. This approach offers a promising direction for therapies that could amplify the role of  
209 natural products in both inflammation and cancer.

### 210 **1.1. Inflammation**

211 Inflammation, derived from Latin term *Inflammati*o, means flame or to set on fire. Hippocrates  
212 in the 5<sup>th</sup> century BCE was the first to identify inflammation a healing response after injury. It  
213 took till the 1<sup>st</sup> century CE for Aulus Celsus to define the four-cardinal signs of inflammation.  
214 Ten centuries later, Ibn Sina (Avicenna) recorded in his encyclopaedia “The canon of medicines”  
215 (al-Qanun fi al-tib) all 5 signs of inflammation and suggested various plants, such as garlic,  
216 chamomile, and saffron, to treat acute inflammation, among other diseases. Building on previous  
217 discoveries, J. Hunter in the 18<sup>th</sup> century CE categorized inflammation into three types: adhesive  
218 inflammation, referring to the formation of the fibrous adhesions between tissues; suppurative  
219 inflammation, characterize by pus formation, an outcome of a severe inflammation; and  
220 ulcerative inflammation, related to the observed open sores due to the tissue loss. In the 19<sup>th</sup>  
221 century CE, a deeper knowledge of inflammation started to be established histologically with the  
222 development of microscopy and thanks to Rudolph Virchow. During this era, the role of  
223 polymorphonuclear leukocytes in the immune response to inflammation was introduced, and  
224 inflammation was then differentiated into 4 types: exudative, infiltrative, parenchymatous and  
225 proliferative. (1–5)

226 Inflammation is a biological response of the body tissue to a harmful stimulus, aimed at repairing  
227 tissues and restoring the internal homeostatic state. There are two types of inflammation: acute  
228 and chronic. Acute inflammation is a short-lived (days to weeks) response usually activated  
229 through injuries or infections. Chronic inflammation is a prolonged and sustained response  
230 (months to years) to persistent infections, autoimmune diseases, neurological conditions,  
231 exposure to toxins or pollutants, and cancer. (4,6,7) (Figure 1)

232 The stimuli that trigger these responses are divided in two major categories: external and internal  
233 factors. External factors can be non-microbial, such as allergens, irritants, and toxic compounds,  
234 or microbial. The microbial factors include the virulence factor that helps pathogens colonize and  
235 infect tissues, and the pathogens associated molecular patterns (PAMPs), which are small  
236 molecules with conserved patterns e.g., peptidoglycan, lipopolysaccharide, lipoteichoic acid,  
237 mannose, and viral RNA/DNA. Internal factors, commonly known as DAMPs or damaged  
238 associated molecular patterns, these are intracellular proteins released from an injured tissue or  
239 dying cells. (8,9) (Figure 1)

240 Moreover, when these patterns (PAMPs and DAMPs) are recognized by pattern recognition  
241 receptors (PRRs), they activate leukocytes, which in turn induce two types of immune responses:  
242 innate and adaptive. The innate response is the first line of defense; it is non-specific, does not  
243 involve immunological memory and lasts few minutes to hours. In contrast, the adaptive  
244 response is antigen-specific, comes second in the line of defense, takes weeks or months to  
245 develop after the initial exposure and creates immunological memory involving T and B cells.

**Figure 1.** Scheme illustrating inflammation. This figure was created with Biorender.com.

Leukocytes (Greek; white cells) are the primary cellular components of the immune system, involved in both innate and adaptive response. They originate from the stem cells in bone marrow and differentiate into myeloblasts and monoblasts, also known as granulocytes and agranulocytes. The monoblasts include lymphocytes (T cells and B cells) and monocytes, which differentiate into macrophages and dendritic cells. The granulocytes, or myeloblasts are characterized with small granules containing proteins. This group includes neutrophils that are most abundant in the blood and are the first to act during acute inflammation. Eosinophils are less present in the blood but have a crucial role in eliminating parasites, asthma, and allergic reactions, in some cases their level increases during an autoimmune disease. Basophils are the least found in the blood and mostly activated when allergic reaction occurs. (Figure 1) Mast cells are granulated cells found predominantly in the connective tissues beneath the epithelium of the skin, gastrointestinal tract, respiratory tract, and surrounded by blood vessels

275 and lymphatic vessels. These cells play a crucial role in the immune system, particularly during  
 276 inflammation. Unlike other granulocytes, mast cells have an important role in both innate and  
 277 adaptive immune responses. Their primary function is in mediating allergic responses, but they  
 278 also exhibit antibacterial, antiparasitic, and antiviral activities. Notably, during adaptive immune  
 279 responses, mast cells contribute to the activation of cytotoxic T cells through the release of TNF-  
 280 alpha and the activation of NF-κB. Additionally, mast cells regulate a variety of physiological  
 281 functions, such as vasodilation, angiogenesis, and the function of various organs and tissues.  
 282 They achieve this by generating and releasing a range of multipotent molecules, including  
 283 histamine, proteases, proteoglycans, leukotrienes, heparin, cytokines, chemokines,  
 284 prostaglandins, and growth factors. These molecules enable mast cells to regulate the function of  
 285 different cells, including dendritic cells, macrophages, T cells, B cells, fibroblasts, eosinophils,  
 286 endothelial cells, and epithelial cells. (12–21) (Figure 2)

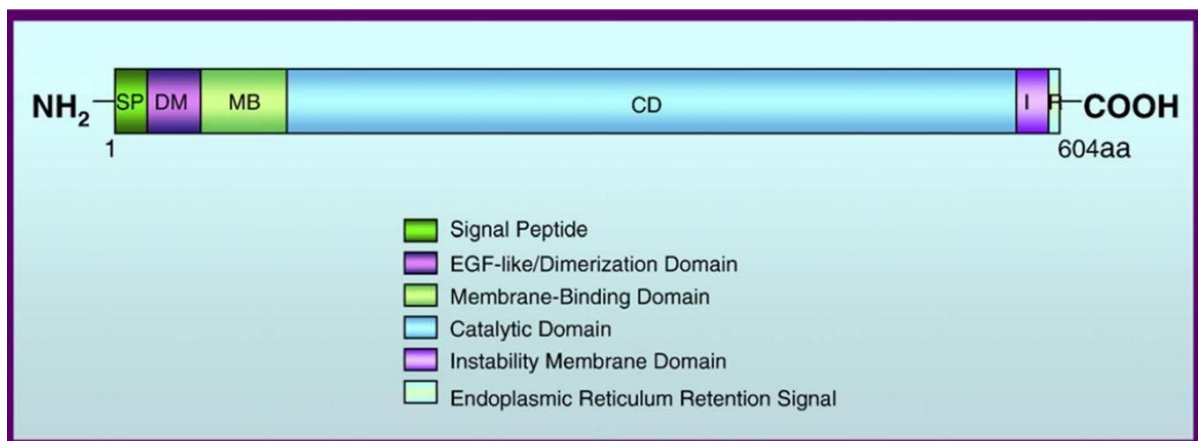

287 **Figure 2.** The function of mast cells in response to inflammation. This figure was created with  
 288 Biorender.com.

### 289 1.1.1 Cyclooxygenase 2

290 Prostaglandin Endoperoxide H Synthase 2 or COX2 is an enzyme isoform of the cyclooxygenase  
 291 from the myeloperoxidase family. It is overexpressed especially during inflammation,

292 carcinogenesis, and tumorigenesis through various factors: cytokines, growth factors, oncogenes,  
293 and tumor promoters. Usually in a stable state it is absent or found at a very low level. (22–24)

294 COX2 is a homodimer enzyme composed of 604 amino acids, constructed of two major domains:  
295 N-terminal domain and C-terminal domain. The N-terminal domain also known as the catalytic  
296 domain, is formed by five key components: a hydrophobic signal peptide directs COX-2  
297 polypeptide into the endoplasmic reticulum (ER) lumen, a 17-amino-acid signal recognition  
298 peptide, dimerization domain containing the epidermal growth factor EGF-like modules the  
299 formation of the COX2 homodimer, membrane binding domain that anchors COX2 to the lipid  
300 bilayer of the ER and nuclear envelope, and the globular catalytic domain features two critical  
301 sites: the COX active site, extending from the membrane binding domain to the hydrophobic  
302 dead-end catalytic domain that contributes to COX2's drug selectivity and substrate binding  
303 flexibility. The peroxidase active site features a cleft that is pivotal for the activation of COX-2.  
304 The C-terminal domain, in contrast, contains 27 amino acids pivotal for the degradation of COX-  
305 2, ending with a small peptide of four amino acids enabling the signal to keep the enzyme in the  
306 ER. (25–29) (Figure 3)

307 **Figure 3.** Illustration of the structure of the human primary protein cyclooxygenase 2. (30)

### 312 **Role of Prostaglandin Endoperoxide H Synthase 2**

313 Cyclooxygenase 2 is a key enzyme responsible for the synthesis of prostaglandins, which play  
314 crucial roles in inflammation, pain, fever and cancer. Once expressed in the endoplasmic  
315 reticulum or in the nuclear envelope membranes, COX2 catalyzes the conversion of arachidonic

316 acid into Prostaglandin G2 (PGG2) through a process of oxidation. In this reaction, COX2  
 317 removes hydrogen from the carbon at position 13 (C13) of arachidonic acid and adds two oxygen  
 318 molecules (O<sub>2</sub>), forming the hydroperoxy endoperoxide PGG2. Subsequently, COX2 further  
 319 reduces PGG2 by two electrons, converting it into Prostaglandin H2 (PGH2), a stable  
 320 intermediate also known as hydroxy endoperoxide. PGH2 is then processed in the cytosol by  
 321 specific synthases to produce various biologically active prostaglandins, including Prostacyclin  
 322 (PGI<sub>2</sub>) and Prostaglandin E2 (PGE2), both of which are important mediators of inflammation  
 323 and are implicated in cancer progression. Notably, COX2 differs from its isomer COX1 in its  
 324 ability to metabolize a broader range of arachidonic acid derivatives, among them  
 325 Endocannabinoid contributing significantly to carcinogenesis and other pathological  
 326 conditions. (22,27,31–38) (Figure 4).

### 330 1.1.2 Nuclear Factor kappa-B (NF-κB)

331 NF-κB is a family of transcription factors. It includes diverse homodimers and heterodimers  
 332 proteins originated from five genes: NF-κB 1 (p50/p105), NF-κB 2 (p52/p100), RelA (p65),  
 333 RelB, cRel (39). The original name of NF-κB is the Nuclear Factor kappa-light-chain-enhancer  
 334 of activated B cells, referring to how it was first discovered in 1986 while investigating the

335 regulation and maturation of B cells essential for the adaptive immune response (40–42).  
 336 Subsequently, NF- $\kappa$ B was found to be involved in diverse biological processes beyond the  
 337 development of B cells such as cell survival and proliferation. Under normal conditions, NF- $\kappa$ B  
 338 dimers are retained in the cytoplasm in an inactive form bound to its inhibitors known as I $\kappa$ Bs  
 339 (Inhibitors of  $\kappa$ B). Activation of NF- $\kappa$ B occurs through two primary signaling pathways: the  
 340 canonical pathway, triggered by cytokines such as tumor necrosis factor-alpha (TNF- $\alpha$ ), and the  
 341 non-canonical pathway, mediated by NF- $\kappa$ B-inducing kinase (NIK). Both pathways converge on  
 342 the I $\kappa$ B kinase (IKK) complex, consisting of IKK $\alpha$ , IKK $\beta$ , and IKK $\gamma$  (NEMO), which  
 343 phosphorylates and induces the degradation of I $\kappa$ B proteins. This degradation releases NF- $\kappa$ B  
 344 dimers, allowing them to translocate to the nucleus where they activate the transcription of genes  
 345 involved in inflammation, immune regulation, cell growth, and survival. Dysregulation of NF- $\kappa$ B  
 346 signaling is implicated in chronic inflammation and various cancers, highlighting its critical  
 347 role in maintaining cellular and immune homeostasis. (43–49) (Figure 5)

348 **Figure 5.** Schematic representation the canonical and non-canonical pathways of NF- $\kappa$ B's  
349 activation, and the three protein families: NF- $\kappa$ B, I $\kappa$ B, and IKK. (50) (Take from: Hayden MS,  
350 Ghosh S. NF- $\kappa$ B in immunobiology. Cell Res. 2011;21(2):223-44. (With the permission of  
351 Springer Nature, and Copyright Clearance Center's RightsLink® service. This work is licensed  
352 under the license number: 5875950938719)

## 353 **1.2 From Inflammation to Carcinogenesis**

354 The link between inflammation and cancer was discovered long time ago. In the 19th century,  
355 the German physician Rudolf Virchow was the first to hypothesize a connection between  
356 inflammation and cancer, observing the presence of leukocytes in tumors and suggesting they  
357 originated from sites of chronic inflammation (51,52). Since then, scientific advancements have  
358 identified the primary components of the tumor microenvironment (TME), which consist of  
359 stromal cells and inflammatory immune cells. This understanding has highlighted the dual role  
360 of the immune system in carcinogenesis, functioning both as a tumor suppressor and a promoter  
361 of tumor growth. The immune system's anti-tumor activity helps limit tumor heterogeneity, while  
362 pro-tumor inflammation supports cancer progression by suppressing anti-tumor immunity  
363 through signaling molecules such as cytokines, interleukins, and chemokines. Key examples  
364 include tumor necrosis factor-alpha (TNF- $\alpha$ ) and interleukin-6 (IL-6) (53,54). Moreover,  
365 inflammatory immune cells, such as tumor-associated macrophages and T-cells within the TME,  
366 have been shown to contribute to cancer growth, invasion, and metastasis (55,56). Notably today,  
367 it is widely accepted that inflammation not only plays a role in carcinogenesis and tumorigenesis  
368 but also aids in the growth and spread of cancer (57–59). This understanding was significantly  
369 advanced by the discovery of the link between the nuclear factor-kappa B (NF- $\kappa$ B) signaling  
370 pathway and tumor cell survival and proliferation. NF- $\kappa$ B is now recognized as a key mediator  
371 in the relationship between chronic inflammation and cancer progression (54,60–63).  
372 Additionally, the role of cyclooxygenase-2 (COX-2) in carcinogenesis was uncovered through  
373 research on non-steroidal anti-inflammatory drugs (NSAIDs). There are clinical studies that  
374 showed the prolonged use of NSAIDs revealed their cancer-preventive and chemopreventive  
375 effects, as they inhibit COX-2, which plays a crucial role in promoting inflammation linked to  
376 tumor development. This finding marked a major advancement in cancer research and prevention  
377 strategies (57,64–69).

378 **Figure 6.** Chronic inflammation initiating cancer-immune cells interaction within tumor  
 379 environment. The illustration highlights the involvement of NF-κB activation and COX2  
 380 overexpression in promoting cell proliferation. (70) (Taken from: Taniguchi K, Karin M. NF-κB,  
 381 inflammation, immunity and cancer: coming of age. Nature Reviews Immunology. 2018;18(5):309-  
 382 24). (With the permission of Nature Reviews Immunology, and Copyright Clearance Center's  
 383 RightsLink® service. This work is licensed under the license number: 5875961439978)

### 384 1.3 Alpha/Beta-Tubulin

385 Microtubules are structural proteins composed of α-tubulin and β-tubulin dimers, forming a key  
 386 component of the cytoskeleton along with microfilaments and intermediate filaments (71,72).  
 387 These three cytoskeletal elements provide structural support to the cell, maintaining its shape,  
 388 adhesion, and motility. Microtubules also play a critical role in intracellular trafficking and  
 389 facilitate cell signaling (73,74). Microtubule assembly is guided by microtubule organizing

390 centers (MTOCs) and  $\gamma$ -tubulin. There are two main types of MTOCs: centrosomes, located near  
391 the nucleus, and basal bodies, found at the base of cilia and flagella on the cell membrane.  
392 MTOCs are essential for organizing microtubules during processes such as chromosome  
393 segregation during cell division, regulation of the cell cycle, and cell proliferation—factors that  
394 are crucial in cancer therapy (75–78). During inflammation, microtubules are essential for the  
395 formation and activation of immune cells, such as T-cells, as they regulate cell signaling  
396 pathways necessary for an effective immune response. Additionally, states of hyperinflammation  
397 and chronic inflammation have been linked to tubulin dysfunction, which have been seen to  
398 contribute to the progression of inflammation into carcinogenesis (79–83).

### 399 **1.3.1 The Interaction Between Tubulin with NF- $\kappa$ B Signaling**

400 Both NF- $\kappa$ B and COX-2 are well-established to play significant roles in both inflammation and  
401 cancer. Studies have also demonstrated a connection between microtubules and inflammatory  
402 proteins. Additionally, research has shown that NF- $\kappa$ B activation enhances signaling in various  
403 inflammatory pathways, including the cGAS-STING (cyclic GMP-AMP synthase-Stimulator of  
404 Interferon Genes) pathway, which is critical for innate and adaptive immune responses. When a  
405 DNA virus enters the cytoplasm, the cGAS enzyme recognizes it and, using ATP and GTP,  
406 synthesizes cyclic GMP-AMP (cGAMP). cGAMP then activates the STING molecule located in  
407 the endoplasmic reticulum (ER). STING translocates to the Golgi apparatus with the help of  
408 microtubules, interacting with COPII vesicles during transport. Once there, STING activates the  
409 I $\kappa$ B kinase (IKK) complex, which phosphorylates I $\kappa$ B, leading to NF- $\kappa$ B activation. NF- $\kappa$ B then  
410 migrates to the nucleus, where it triggers the expression of pro-inflammatory cytokines.  
411 Simultaneously, transcription factor IRF3 (interferon regulatory factor 3) is activated, allowing  
412 for the expression of type I interferons (IFN-I) (84–87). However, in chronic inflammatory  
413 conditions, the overexpression of NF- $\kappa$ B can induce microtubule depolymerization. This inhibits  
414 the proper trafficking of STING to lysosomes for degradation, resulting in prolonged STING  
415 activation and elevated secretion, contributing to sustained inflammation (88–90). (Figure 7)

416 **Figure 7.** The interaction between microtubules and NF-κB during inflammation. (88) (Taken  
 417 from: Zhang L, Wei X, Wang Z, Liu P, Hou Y, Xu Y, Su H, Koci MD, Yin H, Zhang C. NF-κB activation  
 418 enhances STING signaling by altering microtubule-mediated STING trafficking. Cell Reports.  
 419 2023;42(3)). (With the permission Elsevier, and Copyright RightsLink® service. This work is

### 421 1.3.2 The Link Between Tubulin and COX2

422 The relationship between COX-2 and microtubules represents an intriguing area of research with  
 423 potential implications for cancer therapy and cellular biology. Throughout years of research,  
 424 some interesting connections between COX2 and microtubules. Over the years, several studies  
 425 have uncovered intriguing connections between COX-2 and microtubules. Given that  
 426 microtubules regulate cell signaling and molecular trafficking, there is evidence suggesting that  
 427 microtubule dynamics may influence the regulation and localization of COX-2 within the cell.

428 (91–93)

429 Chronic inflammation leads to elevated levels of prostaglandin E2 (PGE2), which acts in an  
430 autocrine manner by binding to and activating EP receptors. This signaling, particularly through  
431 EP2 and EP4 receptors, triggers intracellular cascades that primarily increase cyclic AMP  
432 (cAMP) production, leading to the overexpression of COX-2. This creates positive feedback  
433 loop that amplifies the inflammatory response, eventually contributing to carcinogenesis.  
434 Notably, it has been shown that microtubule disruption interferes with PGE2-induced cAMP  
435 elevation, as microtubules are involved in the trafficking and organization of EP receptors. (94–  
436 100)

437 Research has explored the synergistic effects of combining COX-2 inhibitors with microtubule-  
438 disrupting agents to enhance anti-cancer efficacy. Some studies have even led to the development  
439 of hybrid molecules designed to simultaneously inhibit COX-2 and disrupt microtubules,  
440 potentially offering a novel therapeutic approach. (101–103)

#### 441 **1.4 Mitochondria and ROS Generation**

442 Mitochondria, a membrane-bound organelle, were discovered in the early 1960s and  
443 revolutionized biology not only because they are considered the "powerhouse" of the cell, but  
444 also because they contain their own mitochondrial DNA (mtDNA), which replicates  
445 independently within the cell. These two features make mitochondria essential for various  
446 cellular functions, particularly in energy production, cell differentiation, and apoptosis (104,105).  
447 One of the by-products of mitochondrial activity is reactive oxygen species (ROS), highly  
448 reactive molecules that play dual roles in cellular processes (106). At physiological levels,  
449 mitochondrial ROS (mtROS) act as important signaling molecules, regulating cellular processes  
450 like the adaptive immune response and maintaining cellular homeostasis. However, during acute  
451 or chronic inflammation, excessive ROS production can lead to oxidative stress, damaging  
452 cellular components such as proteins, lipids, and DNA (including mtDNA). This oxidative  
453 damage can result in mitochondrial dysfunction and trigger cell death via apoptosis. (107–113)  
454 The last two decades, Mitochondria have become a central focus in cancer research due to their  
455 role in regulating apoptosis (114). Cancer cells often develop mechanisms to evade mitochondrial  
456 apoptosis, giving them a resistance (115–117). One of the key mechanisms involves altering the  
457 balance between pro-apoptotic and anti-apoptotic proteins in the Bcl-2 family. These proteins  
458 regulate mitochondrial outer membrane permeabilization (MOMP), which changes in  
459 mitochondrial dynamics and morphology. Normally, mitochondria undergo continuous cycles of  
460 fusion and fission, which coordinate their size, shape, and function. When the anti-apoptotic

461 proteins like Bcl-2, Bcl-xL, and Mcl-1 are overexpressed mitochondria tend to stay in a fused  
462 state, which helps them evade degradation by immune cells like macrophages and dendritic cells,  
463 contributing to cancer cell survival. (118–123)

464 Moreover, ROS also play a complex role in cancer. The overproduction of ROS mediate to the  
465 continuous expression of transcription factors like NF- $\kappa$ B and upregulation enzymes like COX-  
466 2. Interestingly, both NF- $\kappa$ B and COX-2 have been associated to the anti-apoptotic pathways that  
467 support cancer cell survival and proliferation, which make them indirectly associated to  
468 regulation of mitochondria's dynamic. (124–131)

### 469 **1.5 Multidrug Resistance**

470 The resistance of cancer cells is not only linked to mitochondrial dynamics but also to their  
471 resistance to cancer treatments. One of the major challenges in cancer therapy occurs when  
472 patients have a resistance to one, or multiple drugs also referred as the Multidrug resistance  
473 (MDR). MDR can be driven by two major categories: intrinsic factors and extrinsic factors.  
474 (132,133) (Figure 8).

475 Intrinsic factors pre-existing within cancer cells before treatment begins. These include genetic  
476 mutations in genes regulating cell death including epidermal growth factor receptor (EGFR) and  
477 p53 gene expressing tumor suppressor protein, drug metabolism, and DNA repair mechanisms.  
478 Such mutations can lead to the sustained production of anti-apoptotic proteins such as Bcl-2, Bcl-  
479 xL, and Mcl-1, as well as an overexpression of membrane transporters like P-glycoprotein (P-  
480 gp) and ATP-binding cassette (ABC) transporters. These transporters are particularly  
481 problematic, as they enhance the efflux of chemotherapeutic compounds, reducing their  
482 intracellular concentrations below effective levels (134–139).

483 Extrinsic factors, on the other hand, emerge during treatment. These may include acquired  
484 resistance after repeated rounds of chemotherapy, changes in the tumor microenvironment  
485 (TME), and conditions like hypoxia (low oxygen levels) or interactions with surrounding stromal  
486 cells (140,141). Inflammation also plays a critical role in extrinsic resistance. Research has  
487 shown that when cancer cells detect chemotherapeutic agents, they activate survival pathways  
488 often associated with inflammatory signaling, where the two proteins NF- $\kappa$ B and COX2 are  
489 found to be consistently overexpressed (142–146). (Figure 9)

490 To overcome multidrug resistance (MDR) in cancer therapy, one of goals is to identify drug  
491 additives, or chemosensitizers, that can be combined with existing chemotherapeutic agents to  
492 enhance their effectiveness. These additives, particularly natural products and their derivatives,

493 are highly preferable due to their ability to target and reverse the mechanisms driving MDR while  
 494 offering the advantage of low cytotoxicity. This makes cancer cells more susceptible to  
 495 chemotherapy with fewer adverse effects on healthy tissues. (147–149)

496 **Figure 8.** Multidrug resistance mechanism under the intrinsic/extrinsic factors. (150) (Taken

## 512 1.6 Chamomile

513 Chamomile has been known for thousands of years, for its various health benefits and therefore  
 514 has been used in the treatment of several conditions thanks to its antioxidant and antimicrobial  
 515 properties (151–153). This plant is considered safe for consumption by the U.S. Food and Drug  
 516 Administration (FDA), which classifies it as generally accepted as safe (GRAS) (154–156).  
 517 Aside from this, chamomile has shown to be very useful in treating muscle spasms, rheumatism,  
 518 and metabolic disorders (157,158). Further, chamomile tea preparations, especially those made  
 519 of German chamomile (*Matricaria chamomilla* L.) have been rich in studies investigating the  
 520 possibility of antidepressant, anti-stress, anti-inflammatory, and anticancer activity (159–163).  
 521 In clinical research studies, chamomile tea extracts have been proven to be effective against

522 inflammation such as inflammatory bowel disease, eczema and mucositis caused by  
523 chemotherapy and radiotherapy (164–166). Additionally, chamomile has shown promise in  
524 alleviating peripheral neuropathic pain, a common side effect of chemotherapy. These anti-  
525 inflammatory and analgesic effects are attributed to chamomile's bioactive compounds, precisely  
526 to its secondary metabolites such as apigenin and  $\alpha$ -bisabolol which have been shown to  
527 modulate inflammatory pathways such as inhibiting the activity of COX2 and NF- $\kappa$ B and  
528 promote healing during both inflammation and cancer (167–174).

### 529 **1.6.1 Chemical constituents and biological activity of *Matricaria chamomilla* L.**

530 German Chamomile (*Matricaria recutita* L.) belongs to the family Asteraceae, native to Europe  
531 and west Asia. is rich in terpenoids ( $\alpha$ -bisabolol, farnesol, chamazulene, luteolin), flavonoids  
532 (apigenin, luteolin, quercetin, myricetin), coumarins (herniarin, umbelliferon), organic acid  
533 (caffeic acid, chlorogenic acid), sterols (stigmasterol, taraxasterol), phenolics (apigenin-7-  
534 glucoside, luteolin-7-glucoside), polysaccharides, volatile oils, polyacetylenes, and mineral.  
535 (152,175–177) (Table 1)

536 These diverse chemical components give the plant a wide range of biological activities. Studies  
537 have demonstrated that flavonoids such as apigenin, luteolin, and chamazulene exhibit anti-  
538 inflammatory effects by inhibiting pro-inflammatory enzymes like cyclooxygenase (COX) and  
539 lipoxygenase, which in turn reduces the production of inflammatory mediators. Free radicals  
540 have been associated with cardiovascular disease and cancer. The high amount of phenolics and  
541 flavonoids like quercetin gave the plant its antioxidant activity that helps neutralize free radicals,  
542 protecting cells from oxidative damage. In addition, the terpenoids in chamomile, particularly  $\alpha$ -  
543 bisabolol, have been shown to have antimicrobial properties, effective against various bacterial  
544 and fungal pathogens. Furthermore, polysaccharide-polyphenolic conjugates isolated from *M.*  
545 *chamomilla* have demonstrated the ability to reduce platelet aggregation in a dose-dependent  
546 manner, without toxic effects on blood cells, suggesting potential applications in treating blood  
547 coagulation disorders In vitro studies have also shown that chamomile flower extract exhibits  
548 cytotoxic activity against cancer cells, including human hepatoma cells (HepG-2) and colorectal  
549 cancer cells (HT-29), by inhibiting nitric oxide (NO) production. Among its many biological  
550 properties. (178–183)

551 Notably, Chamomile poses a long list of biological properties and is renowned for its anti-  
552 inflammatory effects. However, its potential anti-cancer properties have garnered increasing  
553 interest in recent years. Over the past decade, research has demonstrated chamomile's ability to  
554 inhibit cancer cell growth and induce apoptosis (programmed cell death) by regulating key

555 proteins such as COX-2 and NF-κB. These findings raise the potential of chamomile to be used  
556 as an adjuvant to chemotherapy or to help overcome multidrug resistance in cancer treatment.  
557 (Figure 10)

558  
559 **Figure 10.** The biological virtues of *Matricaria chamomilla* L. (184) (Taken from: El Mihaoui  
560 A, Esteves da Silva JC, Charfi S, Candela Castillo ME, Lamarti A, Arnao MB. Chamomile  
561 (*Matricaria chamomilla* L.): a review of ethnomedicinal use, phytochemistry and pharmacological  
562 uses. *Life*. 2022;12(4):479). (With the permission from mdpi. This work is licensed under the

### 565 1.7 Curcumin

566 Curcumin is a natural compound derived from the Turmeric rhizomes of (*Curcuma longa* L). It  
567 is used as spice for cooking but has also a variety of medicinal virtues, it can be found as a  
568 powder, tea, cream, and even capsule. Similar to chamomile, curcumin has many biological  
569 properties including antiviral, antioxidant, anti-bacterial, anti-inflammatory, and anti-cancer.  
570 These properties have intrigued numerous researchers, it has been tested in clinical trials. In  
571 cancer research deep investigations have been led to understand the mechanism of action of this  
572 molecule in cancer cells. Interestingly, curcumin have been found to inhibit cell proliferation,

573 metastasis process and overcome some multidrug resistance mechanisms. Furthermore, it has  
574 been demonstrated that curcumin was positively effective in inhibiting the NF-κB and EGFR  
575 pathways in many cancer types. (185–188)

## 597 **2. Objective of the thesis**

598 In this study, we focused on inflammation and its link to cancer. In human history, we have come  
599 from far, we have made many achievements in the development of technology and medicine.  
600 Nevertheless, there are still millions of people suffering from chronic inflammatory diseases and  
601 millions that are still dying from cancer. In fact, billions of dollars are gained in the industry of  
602 pharma in anti-inflammatory and anti-cancer treatments but still people's suffering is still  
603 ongoing.

604 In that purpose, our focus is on finding alternative treatments that can help overcome these  
605 pharmacological obstacles by using Phyto-pharmaceuticals. Today, natural products have again  
606 gained their place in the market race, over 60% of natural derivatives drugs including the synthetic  
607 compounds that are based on natural pharmacophores, are used as anti-cancer drugs, e.g.,  
608 artemisinin and taxol.

609 Since, chamomile is well known champion used for thousands of years against inflammation. We  
610 wanted to investigate deeper in its effect against cancer and what role can it have in the cancer  
611 therapy. Many chamomile compounds have already been investigated, we wanted to explore the  
612 effect of other compounds that we extracted from the flower of the German chamomile such as  
613 quercetin, luteolin, beta-amyrin, myricetin.

614 Initially, we aimed to investigate the effects of chamomile compounds against COX2, a well-  
615 known anti-inflammatory protein that is primarily induced during inflammation and is often  
616 overexpressed in cancers such as colorectal cancer. Seven chamomile compounds were selected  
617 for testing based on their affinity for COX2, determined through *in silico* molecular docking  
618 studies.

619 Afterwards, we concentrated on myricetin as it stood out from the other six when its cytotoxicity  
620 was analyzed through the NCI60 cell line panel. By performing a cross-resistance profiling of  
621 myricetin from the NCI60 database, we found that myricetin correlated mostly with tubulin  
622 inhibitors such as vincristine. Subsequently, we validated the effect of this molecule on alpha-  
623 tubulin using immunofluorescence microscopy.

624 Moreover, we wanted to know if myricetin was also involved in classical drug resistance.  
625 Consequently, after profiling myricetin in drug resistance mechanisms using the NCI60 cell line  
626 panel, we verified *in vitro* that it was not involved in multidrug resistance mechanisms.

627 Finally, we wanted to emphasize the utility of finding a potential COX2 inhibitor like myricetin  
628 by demonstrating that COX2 plays an important role in cancer. We found that its high expression

629 is associated with worse survival prognosis of renal clear cell carcinoma patients, utilizing  
630 Kaplan-Meier survival time analysis.

631 Lastly, NF- $\kappa$ B is a renowned anti-inflammatory and anti-apoptotic protein, which has long been  
632 researched for its involvement in the survival and proliferation of cancer cells. In a similar pattern  
633 as mentioned above, we tested the affinity of chamomile compounds with the NF- $\kappa$ B (p65/RelA)  
634 protein and selected six of them to confirm their inhibitory effect against the protein using an  
635 NF- $\kappa$ B inhibitor assay. Since mitochondria and ROS generation have been demonstrated to be  
636 involved in cancer and linked to NF- $\kappa$ B, we were curious if our top compound,  $\beta$ -amyryn, had  
637 any effect on them.

638 After performing various -omics analyses using the NCI60, we chose lupeol and quercetin to  
639 verify the findings *in vitro* by performing immunofluorescence microscopy of  $\alpha$ -tubulin,  
640 resazurin assay, apoptosis, and cell cycle analysis.

641 Furthermore, the role of NF- $\kappa$ B in promoting the expression of genes during inflammation and/or  
642 carcinogenesis, such as the production of cytokines and interleukins, was investigated. Therefore,  
643 we performed a real-time PCR assay to prove that the three selected compounds could indeed  
644 inhibit IL-6 and IL-1 $\beta$  during inflammation. Additionally, we wanted to test that the three  
645 molecules do inhibit NF- $\kappa$ B by conducting a western blot using total cellular NF- $\kappa$ B extracted  
646 from the induced inflammatory cells, HEK-Blue Null 1.

647 Finally, we explored if NF- $\kappa$ B overexpression would have an impact on the survival of patients  
648 afflicted with renal clear carcinoma using the KMPlotter database.

649 As supplementary project related to the above-mentioned NF- $\kappa$ B study. We focused on curcumin  
650 and its 50 derivatives, exploring their effects on NF- $\kappa$ B and EGFR *in silico* and *in vitro*. In  
651 addition to their bioactivity within cancer cells, through resazurin assays, lactate dehydrogenase  
652 assay, flow cytometric measurement of reactive oxygen species, and annexin V/propidium iodide  
653 assay.

654

655 **3. Results and Discussion**

656 More than 200 chamomile compounds were extracted from the flower of the German chamomile  
657 and were analysed using liquid chromatography diode array detector-quadrupole time-of-flight  
658 mass spectrometry (LC-DAD-QToF). These compounds were then studied with two prompt anti-  
659 inflammatory proteins Cyclooxygenase2 and the Nuclear transcription factor kappa B.

660 **3.1 COX2-Inhibitory and Cytotoxic Activities of Phytoconstituents of *Matricaria***  
661 ***chamomilla* L.**

662 A total of 212 ligands found in chamomile were virtually screened against the enzyme COX2.  
663 Among these,  $\beta$ -sitosterol exhibited the highest binding affinity, with a docking score of -11.73  
664 ( $\pm 0.44$ ) kcal/mol. This result was consistent with the COX2 inhibition screening assay,  
665 confirming the strong interaction between the selected compounds and COX2.

666 The resazurin assays demonstrated that chamomile extract effectively inhibited hematopoietic  
667 cancer cell lines CCRF-CEM and AMO-1, with  $IC_{50}$  values  $3.7 \pm 4.7 \mu\text{g/ml}$  to  $28.0 \pm 2.2 \mu\text{g/ml}$ ,  
668 respectively. However, the extract was not effective against the resistance of the colon cancer cell  
669 line HCT116 p53<sup>-/-</sup> knockout, with an  $IC_{50}$  of  $74.3 \pm 0.4 \mu\text{g/ml}$ , indicating a resistance 2.65 times  
670 greater than that of the wild-type HCT116 p53<sup>+/+</sup> ( $IC_{50}$  of  $28.0 \pm 2.2 \mu\text{g/ml}$ ).

671 Further analysis of the NCI60 cancer cell line panel identified apigenin, farnesol, and myricetin  
672 as the most active compounds. Given that apigenin and farnesol had already been studied by our  
673 group, we focused on myricetin. Oncobiogram analysis revealed that myricetin's bioactivity  
674 significantly correlated with 5 of 10 tubulin inhibitors and 2 of 14 tyrosine kinase inhibitors.  
675 Immunofluorescence microscopy of GFP-tagged  $\alpha$ -tubulin confirmed that myricetin inhibits  
676 microtubules in a manner similar to vincristine.

677 The number one issue in cancer therapy is multidrug resistance. Through drug resistance profiling  
678 using NCI60 data, myricetin demonstrated cross-resistance only with classical anticancer drugs  
679 linked to glutathione S-transferase P (GSTP) activity and cellular proliferation rates. This finding  
680 suggests that other chamomile components, rather than myricetin, might be responsible for the  
681 resistance observed in HCT116 p53<sup>-/-</sup> knockout cells when treated with the plant extract.  
682 Additionally, proteomics analysis identified several proteins responsive to myricetin that may be  
683 involved in its mode of action and multidrug resistance mechanisms. These proteins include those  
684 involved in mRNA metabolism (e.g., DDX39B, CSNK2A), programmed cell death (e.g.,  
685 TP53I3, PDCD5), and genome stability (e.g., CDK2, BLM).

686 Finally, Kaplan-Meier survival analysis using the KMPlotter database revealed that COX2  
687 overexpression correlates with poorer survival in patients with renal clear cell carcinoma. This

688 finding accentuates the potential therapeutic value of identifying a strong COX2 inhibitor to  
689 improve patient outcomes.

691 **3.2 Anti-Inflammatory and Cancer-Preventive Potential of Chamomile (*Matricaria***  
692 ***chamomilla* L.): A Comprehensive *in Silico* and In Vitro Study**

693 The molecular docking of 212 phytochemicals found in chamomile against NF- $\kappa$ B revealed that  
694  $\beta$ -amyryn had the highest affinity for the protein ( $-8.70 \pm <0.01$  kcal/mol, pKi  $0.42 \pm < 0.01$   $\mu$ M).  
695 These molecular docking results were further confirmed using microscale thermophoresis, which  
696 demonstrated that  $\beta$ -amyryn binds to NF- $\kappa$ B with a  $K_D$  value of  $943 \pm 113$  nM. The results also  
697 significantly correlated with the NF- $\kappa$ B reporter assay, showing that  $\beta$ -amyryn was the most  
698 potent inhibitor of NF- $\kappa$ B, achieving 61.1% ( $\pm 7.3$ ) inhibition at 10  $\mu$ M.

699 Additionally, an oxidative stress assay revealed that  $\beta$ -amyryn was effective in reducing ROS  
700 generation in an inflammatory state with elevated oxidative stress, with reductions of 12.30% ( $p$   
701  $= 0.1$ ), 10.83% ( $p = 0.05$ ), and 8.80% ( $p = 0.01$ ) at concentrations of 0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M,  
702 respectively. To assess its effect on mitochondrial membrane potential, we used HEK-Blue Null1  
703 cells under induced inflammation.  $\beta$ -amyryn led to apoptosis in 52.6% of the cell population,  
704 while 47.6% of the cells remained viable. Conversely, the resazurin assay showed that  $\beta$ -amyryn  
705 was not cytotoxic to CCRF-CEM leukemia cells. Interestingly,  $\beta$ -amyryn was not included in the  
706 NCI60 database. Therefore, following the cytotoxicity analysis, we selected lupeol and quercetin,  
707 the next most cytotoxic chamomile compounds identified in the NCI60 panel. Moreover, the  
708 oncobiogram analysis revealed that both compounds correlated with microtubule inhibitors. This  
709 was confirmed by immunofluorescence microscopy, which showed that both lupeol and  
710 quercetin inhibited the polymerization of  $\alpha$ -tubulin at 10  $\mu$ M. *In silico* docking studies further  
711 supported these findings, showing that lupeol and quercetin had a higher affinity for  $\alpha$ -tubulin  
712 when docked in the vincristine pocket ( $-8.62 \pm 0.04$  kcal/mol for lupeol and  $-6.77 \pm 0.06$   
713 kcal/mol for quercetin) compared to paclitaxel and colchicine. Both compounds' impact on  
714 microtubules was also reflected in their ability to arrest the U2OS cell cycle at the G2/M phase  
715 after 72 hours of treatment at 4x IC50. The cytotoxicity of lupeol and quercetin was further tested  
716 *in vitro* using the resazurin assay, which demonstrated toxic activity against leukemia,  
717 glioblastoma, and colorectal cancer cell lines. However, osteosarcoma cells were more resistant  
718 to these compounds. Notably, knockout cells of P-glycoprotein, EGFR, and TP53 showed  
719 reduced or no resistance to lupeol and quercetin compared to conventional cancer drugs. This  
720 finding substantiated our bioinformatic analyses, suggesting that neither compound is associated  
721 with cross-resistance mechanisms. An apoptosis assay on CCRF-CEM and U2OS cells  
722 reaffirmed that lupeol and quercetin induced apoptosis in hematopoietic cells but had no effect  
723 on osteosarcoma cells.

724 Lastly, RT-PCR analysis showed that  $\beta$ -amyryn, quercetin, and lupeol significantly

725 downregulated the expression of inflammatory genes. While western blot analysis revealed that  
726 only  $\beta$ -amyryn and quercetin inhibited NF- $\kappa$ B activity.  
727 In light of these findings, Kaplan-Meier analysis emphasized the correlation between NF- $\kappa$ B  
728 overexpression and the short survival time of patients with renal clear cell carcinoma,  
729 highlighting the importance of discovering novel NF- $\kappa$ B inhibitors.  
730

731 **3.3 Side project:**

732 **In Silico and In Vitro Screening of 50 Curcumin Compounds as EGFR and NF-κB**

733 **Inhibitors**

734 The 50 curcumin analogues were screened in silico to calculate their binding affinity with NF-  
735 κB and EGFR using molecular docking. The binding affinities of the ligands to EGFR and NF-  
736 κB proteins were found to be similar. For EGFR, the binding energy values ranged from -12.12  
737 (±0.21) to -7.34 (±0.07) kcal/mol, with pKi values between 0.00013 (±0.00006) and 3.45 (±0.10)  
738 μM. For NF-κB, the binding energies ranged from -12.97 (±0.47) to -6.24 (±0.06) kcal/mol,  
739 with pKi values from 0.0004 (±0.0003) to 10.05 (±4.03) μM. Interestingly, 20 of these  
740 compounds showed better affinity for both targets than curcumin, indicating that these  
741 derivatives may be better candidates than curcumin as anticancer drug agents. These results were  
742 further validated using microscale thermophoresis. The bioactivity of curcumin, N-(3-  
743 nitrophenyl pyrazole), and 1A9 was then explored, revealing that the cytotoxicity of the two  
744 analogue candidates was higher than that of curcumin. Notably, the N-(3-nitrophenylpyrazole)  
745 derivative induced higher ROS generation but did not activate apoptosis, unlike curcumin and  
746 1A9. This suggests that N-(3-nitrophenylpyrazole) and other curcumin derivatives may provoke  
747 cell death through different downstream and ROS-dependent mechanisms. Insightfully,  
748 compounds such as N-(3-nitrophenylpyrazole) could be promising cancer treatments due to their  
749 ability to bypass apoptosis and target apoptosis-resistant tumors.

750 Overall, this study presents an optimistic outlook for curcumin derivatives in cancer therapy.

759

760 **4. Conclusion**

761 The need to discover novel therapeutic drugs to treat inflammation and cancer has become more  
762 urgent than ever. The natural products play a crucial role in the treatment and prevention of these  
763 conditions due to their bioactive compounds. Importantly, they are known to exhibit lower  
764 cytotoxicity and fewer side effects than the conventional synthetic drugs. In this research, we  
765 demonstrated the ability of chamomile compounds and curcumin analogues to act through  
766 multiple mechanisms, such as inducing apoptosis, reducing oxidative stress, regulating  
767 mitochondrial membrane potential, modulating immune responses, and even overcoming  
768 multidrug resistance. This highlights their versatility and their potential as anti-inflammatory and  
769 cancer preventive agents.

770 Continued research into these compounds may lead to novel, effective treatments, offering hope  
771 as alternatives to conventional therapies.

**Abstract:** Chamomile tea is a popular beverage and herbal remedy with various health benefits, including antioxidant and antimicrobial activities and beneficial effects on metabolism. In this study, we investigated the inhibitory activities of secondary metabolites from *Matricaria chamomilla* L. against COX2, an enzyme involved in inflammation and linked to cancer development. The cytotoxicity of the compounds was also evaluated on a panel of 60 cancer cell lines. Myricetin, one of the COX2-inhibiting and cytotoxic compounds in chamomile tea, was further studied to determine a proteomic expression profile that predicts the sensitivity or resistance of tumor cell lines to this compound. The expression of classical mechanisms of anticancer drug resistance did not affect the responsiveness of cancer cells to myricetin, e.g., ATP-binding cassette (ABC) transporters (ABCB, ABCB5, ABCC1, ABCG2), tumor suppressors (p53, WT1), and oncogenes (EGFR, RAS), whereas significant correlations between myricetin responsiveness and GSTP expression and cellular proliferation rates were observed. Additionally, Kaplan–Meier survival time analyses revealed that high COX2 expression is associated with a worse survival prognosis in renal clear cell carcinoma patients, suggesting a potential utility for COX2 inhibition by myricetin in this tumor type. Overall, this study provides insight into the molecular modes of action of chamomile secondary metabolites and their potential as cancer-preventive or therapeutic agents.

**Keywords:** anti-inflammatory activity; beverages; cancer; chemoprevention; proteomics; tea

## 1. Introduction

Chamomile tea is widely known for its medicinal properties and is commonly used in traditional medicine for its antioxidant and antimicrobial activities [1,2]. In addition, Chamomile tea is also recognized for its value as a food due to its beneficial effect on metabolism, especially in the kidneys and liver. The safe use of chamomile was approved by the U.S. Food and Drug Administration (FDA's GRAS) [3,4]. Several studies have shown the effect of chamomile against muscle spasms, rheumatism, and gastrointestinal disorders [5,6]. Furthermore, extensive literature promotes the effect of chamomile tea, such as the German chamomile *Matricaria chamomilla* L., against obesity, depression, stress, inflammation, and cancer [7–12]. Moreover, different clinical trials demonstrated not only the anti-inflammatory effect against eczema as well as chemo- and radiotherapy-induced mucositis by a chamomile tea extract and its bioactive secondary metabolites, apigenin and  $\alpha$ -bisabolol [13,14]. Furthermore, analgesic effects have been shown against peripheral neuropathic pain, a side effect from chemotherapy, and apoptotic activity by inhibiting COX2 and NF- $\kappa$ B [15,16].

The German chamomile (*M. chamomilla* L., syn. *Matricaria recutita* L.) and Roman chamomile (*Chamaemelum nobile* L. (All)) are the most known chamomile species. They are both rich in flavonoids, phenolic acids, and terpenoids. The German chamomile contains more terpenoids and is more resistant to pathogens [17]. Furthermore, its flower extract

contained more of these components than tea and essential oil [18]. Apigenin was one of the first compounds extracted from chamomile [19], which has been studied in the past for its anti-carcinogenic and anti-apoptotic effects [20–22]. The compounds inhibit cancer cell proliferation by blocking the activity of numerous proteins, including RelA/p65 and COX2 [23,24].

COX2 is an important enzyme that plays a key role in inflammation. It is involved in the production of prostaglandins, which promote inflammation. Inflammation is a necessary process for the body's immune response against infection or injury, but if it becomes chronic, it can lead to a range of health problems, including cancer [25–28].

Our aim in this study was to investigate the molecular modes of action of secondary metabolites extracted from *M. chamomile* in terms of their inhibitory activity against COX2 and their cytotoxicity towards a panel of 60 cell lines from the National Cancer Institute. Then, we focused on myricetin, one of the COX2-inhibiting and cytotoxic chemical constituents of chamomile tea, to determine a proteomic expression profile that predicts the sensitivity or resistance of tumor cell lines to this compound. Finally, we mined the KM Plotter database to identify tumor types where high COX2 expression is associated with a worse Kaplan–Meier survival prognosis in cancer patients in an endeavor to envision a clinical situation where COX2 inhibition by myricetin might exert preventive or therapeutic potential.

## 2. Materials and Methods

### 2.1. Phytochemical Analysis

#### Chemicals

Nine standards were used as reference compounds. The compounds were *cis*-GMCA [(Z)-2- $\beta$ -D-glucopyranosyloxy-4-methoxycinnamic acid] (2), *trans*-GMCA [(E)-2- $\beta$ -D-glucopyranosyloxy-4-methoxycinnamic acid] (4), quercetagenin-7-O- $\beta$ -D-glucopyranoside (3), apigenin-7-O- $\beta$ -D-glucoside (6), apigenin 7-O-(6''-O-acetyl- $\beta$ -D-glucopyranoside) (7), tonghosu [2-(2',4'-hexadiynylidene)-1,6-dioxaspiro [4,4]-non-3-ene] (9) were isolated at the National Center for Natural Products Research (NCNPR), University of Mississippi, Oxford, MS, USA. The identity and purity of these compounds are confirmed by chromatographic (TLC, HPLC) methods, and the analysis of the spectral data (IR, 1D- and 2D-NMR, ESI-HRMS) in comparison with published spectral data is also confirmed. The purity of these isolated compounds was found to be greater than 95%. Chlorogenic acid (1) and apigenin (8) were purchased from Chromadex (Santa Ana, CA, USA, purity greater than 97%). Luteolin-7-O- $\beta$ -D-glucoside (5) was purchased from Indofine Chemical Company, Inc. (Hillsborough, NJ, USA, purity greater than 97%). Acetonitrile and formic acid were of HPLC grade and purchased from Fisher Scientific (Fair Lawn, NJ, USA). Water for the HPLC mobile phase was purified using a Milli-Q system (Millipore) [29].

### 2.2. Instrumentation and Chromatographic Conditions of Liquid Chromatography with a Diode Array Detector–Quadrupole Time-of-Flight Mass Spectrometry (LC–DAD–QToF)

The phytochemical analysis using liquid chromatography–diode array detector–quadrupole time-of-flight mass spectrometry (LC–DAD–QToF) was performed according to recently published protocols [29,30]. An Agilent 1290 Series liquid chromatographic system was used (Agilent Technologies, Santa Clara, CA, USA), comprising a binary pump, a vacuum solvent degasser, an autosampler with 108-vial well-plate trays, a thermostatically controlled column compartment, and a diode array detector. The separation was achieved on an Agilent Poroshell 120 EC-C18 column (150 mm  $\times$  2.1 mm I.D., 2.7  $\mu$ m). The mobile phase consisted of water with 0.1% formic acid (A) and acetonitrile with 0.1% formic acid (B) at a flow rate of 0.25 mL/min. Analysis was performed using the following gradient elution: 90% A/10% B to 60%A/40%B in 15 min; in the next 15 min to 100% B. Each run was followed by a 5-min wash with 100% B and an equilibration period of 5 min with initial conditions of 90% A/10% B. One microliter of sample was injected, and the column temperature was maintained at 40 °C. The mass spectrometric analysis was performed with

a QToF-MS (Model #G6545B, Agilent Technologies, Santa Clara, CA, USA) equipped with an ESI source using the following parameters: drying gas (N<sub>2</sub>) flow rate, 13 L/min; drying gas temperature, 325 °C; nebulizer pressure, 35 psig; sheath gas temperature, 300 °C; sheath gas flow, 11 L/min; capillary voltage, 3500 V; nozzle voltage, 0 V; skimmer, 65 V; Oct RF V, 750 V; and fragmentor voltage, 175 V. All the operations, acquisition, and analysis of data were controlled using Agilent MassHunter Acquisition Software Ver. A.10.1 and processed with MassHunter Qualitative Analysis Software Ver. B.7.00. Each sample was analyzed in positive and negative modes over the range of  $m/z = 100$ – $1700$  and extended dynamic range (flight time to  $m/z$  1700 at a 2 GHz acquisition rate). Accurate mass measurements were obtained by means of reference ion correction using reference masses at  $m/z$  121.0509 (protonated purine) and 922.0098 [protonated hexakis (1H, 1H, 3H-tetrafluoropropoxy) phosphazine, or HP-921] in positive ion mode. The UV detection wavelength was in the range of 200–500 nm. The phytochemical analysis with UHPLC–DAD–QToF was performed according to recently published protocols [29,30].

### 2.3. Virtual Drug Screening and Molecular Docking

A list of more than 1000 chamomile compounds was first screened *in silico* against COX2 using PyRx [31,32]. The COX2 crystal structure was taken from the Protein Data Bank (PDB ID: 5F1A) [33,34]. This structure was prepared for virtual drug screening using the Chimera software [35]. We cut the crystal structure and used chain A within the catalytic domain of 5F1A. Using AutoDockTools-1.5.7rc1 [34], water molecules were deleted, polar hydrogen atoms were added and merged, the missing atoms and bonds were repaired, and Kollman charges were added.

After performing the virtual screening with PyRx, 211 ligands from more than 1000 compounds were selected and subjected to molecular docking against COX2 using Autodock 4.2.6 [36–38]. A Grid-box was set based on the interaction of the known COX2 ligand salicylic acid with the amino acids of COX2-5F1A [39]. Its dimensions were  $104 \times 70 \times 100$  Å spacing 0.369 Å the Grid-center  $x = 45.667$  Å,  $y = 28.779$  Å and  $z = 232.841$  Å. The Lamarckian Genetic Algorithm (LGA) was applied to seek the lowest binding energies (LBE, kcal/mol) and predicted inhibition constants ( $pK_i$ ,  $\mu M$ ) with docking parameters set to 250 runs and 2,500,000 energy evaluations for each cycle. Mean values  $\pm$  SD were calculated from each of the three independent dockings. BIOVIA Discovery Studio Visualizer 2021 [40] was used for the 3D visualization pictures of the interaction between the ligands and the amino acids of the crystal structure of COX2.

A total of 207 samples from chamomile was included in this present study (Supplementary Table S1).

### 2.4. Fluorometric COX2 Inhibitor Screening Assay

To validate the *in silico* results from virtual drug screening, we performed an *in vitro* COX2 inhibitor assay (BioVision Incorporate Berlin, Germany [41]) according to the manufacturer's instructions. The assay is based on the fluorometric detection of prostaglandin G<sub>2</sub>, which is produced by the conversion of arachidonic acid by the catalytic activity of COX2. Selected phytochemicals of chamomile tea (apigenin,  $\beta$ -amyryn,  $\beta$ -eudesmol,  $\beta$ -sitosterol, daucosterol, farnesol, and myricetin) were chosen based on their LBE values from virtual drug screening. These compounds were tested for their COX2 inhibition *in vitro* at concentrations of 0.1  $\mu M$  and 1  $\mu M$ .

### 2.5. Pharmacological Testing and Gene/Protein Expression Profiling of Tumor Cell Lines

The Developmental Therapeutics Program of the National Cancer Institute (Bethesda, MA, USA) [42] used a series of human tumor cell lines from diverse origins (leukemia, melanoma, brain tumors, and carcinoma of the lung, colon, kidney, ovary, breast, or prostate) for drug screening [43]. The data of compound screening ( $\log_{10}IC_{50}$  values obtained by a sulforhodamine 123 assay) as well as transcriptomic and proteomic expression

data were deposited at the NCI website [44]. For statistical correlation analyses, we used Pearson's correlation test (WinStat, Kalmia Inc., Cambridge, MA, USA).

#### 2.6. Growth Inhibition Assay

Resazurin reduction assay was conducted to measure the growth inhibitory activity of *Chamomilla matricaria* L. Human CCRF-CEM leukemia and human AMO1 multiple myeloma cells were seeded at a density of  $1 \times 10^4$  cells per well in 96-well plates using 100  $\mu$ L of RPMI 1640 medium. These cells were then treated with the extract at 7 different concentrations, each diluted in 100  $\mu$ L of medium, and incubated for 72 h. Similarly, HCT116 p53<sup>+/+</sup> wildtype and drug-resistant HCT p53<sup>-/-</sup> knockout colon cancer cells were seeded ( $5 \times 10^3$  cells/well) in 100  $\mu$ L DMEM medium and allowed to adhere for 24 h. The next day, these cells were treated with the same series of extract concentrations and incubated for an additional 48 h [45]. On the final day of incubation, 20  $\mu$ L of 0.01% resazurin solution from Promega (Mannheim, Germany) was added to each well and left to incubate for over 4 h at 37 °C. The fluorescence signal was then measured at an excitation wavelength of 544 nm and an emission wavelength of 590 nm using the Infinite M2000 Pro-plate reader from Tecan (Crailsheim, Germany). The experiment was independently replicated three times, and each concentration was tested with six replicates. The growth inhibitory effect of the treatment was represented as the percentage of cell viability and graphed as a dose–response curve. The IC<sub>50</sub> value representing the concentration at which the growth was inhibited by 50% was calculated using Microsoft Excel 2021 (Version 2306 Build 16.0.16529.20164) [46].

#### 2.7. Kaplan–Meier Survival Analysis

Data from more than 30,000 samples of 21 tumor types are deposited in the KMPlotter database [47–49]. The Kaplan–Meier statistics algorithm of this database was used to identify the prognostic value of COX2 mRNA expression for the survival time of cancer patients. We used a false discovery rate (FDR) calculation to exclude type I errors in multiple comparisons [50]. We included only Kaplan–Meier statistics with FDR rates  $\leq 5\%$ , indicating that not more than 5% of “declared” positive results were truly negative.

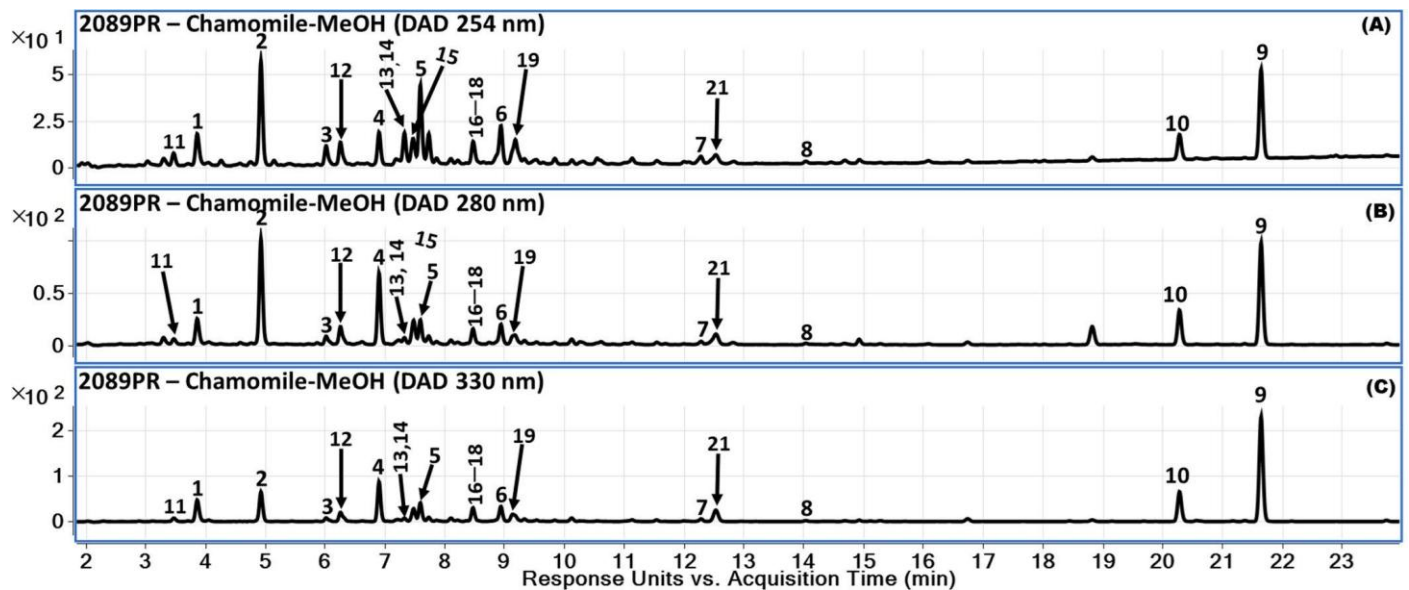

#### 2.8. Immunofluorescence Microscopy of GFP Tagged $\alpha$ -Tubulin

Human U2OS osteosarcoma cells were left to attach for 24 h in  $\mu$ -Slide 8 Well (30,000 cells/well) (ibidi, Gräfelfing, Germany). The next day, the cells were treated with myricetin (0.1, 1, 10  $\mu$ M) (Sigma-Aldrich Chemie GmbH, Taufkirchen, Germany) as well as paclitaxel (1  $\mu$ M) and vincristine (1  $\mu$ M) (both of the drugs were a gift from the pharmacy of the university hospital Johannes Gutenberg Mainz, Germany) as positive controls, along with DMSO as a negative control. After 24 h, cells were washed with PBS, fixed with 4% paraformaldehyde, and stained with 1  $\mu$ g/mL of 4',6-diamidino-2-phenylindole (DAPI, Sigma Aldrich, Darmstadt, Germany) in the dark. Subsequently, the slides were immersed in Mounting Medium (ibidi, Gräfelfing, Germany). Widefield imaging was performed using a THUNDER Imager Live Cell (Leica Microsystems, Wetzlar, Germany) based on a Leica DMi8 microscope stand. Both transmission light and fluorescence images were acquired using a 63 $\times$ /1.40 NA objective (HC PL APO CS2 63 $\times$ /1.40 OIL UV). Fluorescence was excited with an LED light source (LED8, Leica) at 395 nm and 488 nm for imaging of DAPI and Tubulin–GFP, respectively. A quadband filter cube (DFT51010, Leica) split fluorescence excitation and emission light, and additional emission filters (460/80 for imaging of DAPI signals and 535/70 for imaging of GFP signals) were used to reduce bleed-through. The camera (Leica DFC9000 GTC) was operated in 2  $\times$  2 binning mode, resulting in a pixel size of 206 nm measured in the object plane. Exposure times were set to 200 ms (GFP–Tubulin), 25 ms (DAPI), and 150 ms (differential interference contrast (DIC)). Images were analyzed with Image J software (National Institute of Health, Bethesda, MD, USA). The methodology of this experiment was described by us [51] and the microscopy techniques by Marton Gelléri (Institute of Molecular Biology gGmbH (IMB), Mainz, Germany).

### 3. Results

#### 3.1. Phytochemical Analysis

The phytochemical analysis of chamomile extract was conducted using liquid chromatography–diode array detector–quadrupole time-of-flight mass spectrometry (LC–DAD–QToF). As shown in Figure 1, 21 phytochemicals were tentatively detected.

**Figure 1.** Typical LC–DAD chromatogram (absorbance vs. retention time) of a tea sample (*Matricaria chamomilla* L.) at 254 nm (A), 280 nm (B) and 330 nm (C): chlorogenic acid (1), *cis*-GMCA [(*Z*)-2- $\beta$ -D-glucopyranosyloxy-4-methoxycinnamic acid] (2), quercetagenin-7-*O*- $\beta$ -D-glucopyranoside (3), *trans*-GMCA [(*E*)-2- $\beta$ -D-glucopyranosyloxy-4-methoxycinnamic acid] (4), luteolin-7-*O*- $\beta$ -D-glucoside (5), apigenin-7-*O*- $\beta$ -D-glucoside (6), apigenin 7-*O*-(6''-*O*-acetyl- $\beta$ -D-glucopyranoside) (7), apigenin (8), and isomers of tonghaosu [2-(2',4'-hexadiynylidene)-1,6-dioxaspiro [4,4]-non-3-ene] (9–10), esculin (11), isoquercitrin (12), lolilide/isololilide (13–14), quercitrin (15), 3,5-di-caffeoylquinic acid (16–18), isorhamnetin 3-*O*- $\beta$ -D-glucopyranoside (19), quercetagenin 4'-methyl ether 7-(6-*E*-caffeoylglucoside) (20), glucuronolactone (21), and myricetin (22). All compounds were assigned based on mass spectrometry.

#### 3.2. Cytotoxicity Assay

To examine the activity of chamomile extract against cancer cell lines, we have conducted growth inhibition assays. The extract revealed cytotoxicity against different cancer types. The  $IC_{50}$  values of the two hematopoietic cell lines CCRF-CEM and AMO1 ( $23.7 \pm 4.7 \mu\text{g/mL}$  to  $28.0 \pm 2.2 \mu\text{g/mL}$ ) were lower than those of the colon cancer cell lines. Wildtype HCT116 p53<sup>+/+</sup> had an  $IC_{50}$  value of  $28.0 \pm 2.2 \mu\text{g/mL}$ , and HCT116 p53<sup>-/-</sup> knockout cells had an  $IC_{50}$  value of  $74.3 \pm 0.4 \mu\text{g/mL}$ . Hence, the p53 knockout cells were 2.65-fold more resistant to the chamomile extract than the p53 wild-type cells (Figure 2).

**Figure 2.** Dose–response curve of the extract of chamomile in hematopoietic and colon cancer cell lines determined by a resazurin assay. **(A)** Growth inhibition of CCRF-CEM leukemia cells and AMO-1 multiple myeloma cells. **(B)** Growth inhibition of HCT116 p53<sup>+/+</sup> wildtype and drug-resistant HCT116 p53<sup>-/-</sup> knockout cells. The IC<sub>50</sub> values were determined from the dose–response curve, and the degree of resistance was obtained by dividing the IC<sub>50</sub> value of HCT p53<sup>-/-</sup> by the IC<sub>50</sub> value of HCT p53<sup>+/+</sup>. The mean values  $\pm$  standard deviation values are from three independent experiments.

### 3.3. Molecular Docking In Silico

To investigate the full potential of chamomile tea, a total of 212 chamomile compounds were docked against human COX2 (PDB: 5F1A) using the PyRx program. Thirty of these 212 compounds were selected as the most abundant for further analysis. Table 1 shows the low binding energies (LBE, kcal/mol) and the predicted inhibition constants (pKi,  $\mu\text{M}$ ) of these 30 ligands. The LBE and pKi values of these phytochemicals correlated significantly with each other (Pearson correlation test,  $p = 7.53 \times 10^{-20}$ ;  $r = 0.574$ ; Figure 1, 1st line left panel). The LBE values of 27 out of 30 substances were smaller than  $-6$  kcal/mol (cut-off) and ranged from  $-11.73 (\pm 0.44)$  kcal/mol ( $\beta$ -sitosterol) to  $-6.01 (\pm <0.01)$  kcal/mol (P-cymene). The pKi values of these 27 compounds were in a range from  $0.003 (\pm 0.002)$   $\mu\text{M}$  to  $39.57 (\pm <0.01)$   $\mu\text{M}$ . Seven of the 27 compounds were selected because these substances were found in the NCI database ([dtp.cancer.gov](http://dtp.cancer.gov), accessed on 1 July 2023), whose data are required for further investigations. Celecoxib was used as a positive control drug since it is a well-known COX2 inhibitor. As shown in Figure 3 (1st line, middle, and right panel), the compounds were bound to three domains of COX2. Myricetin, daucosterol, and  $\beta$ -amyrin interacted with the first domain;  $\beta$ -sitosterol, apigenin, farnesol, and  $\beta$ -eudesmol with the second domain; and celecoxib with the third domain. Lines 2–5 of Figure 1 depict the three-dimensional binding poses of the compounds and the interacting amino acids.

**Table 1.** Molecular docking of 30 chamomile compounds binds to COX2 (PDB ID: 5F1A). Shown are the lowest binding energies (kcal/mol), predicted inhibition constants ( $\mu\text{M}$ ), and the pharmacophores interacting between the ligands and COX2. Bold indicates hydrogen bonds.

**Figure 3.** Molecular docking analysis of 7 compounds derived from chamomile (*Matricaria chamomilla*) and celecoxib to COX2 (5F1A). They were bound to different pockets within the same domain. The three red circles indicate the different binding sites. The low binding energy (Kcal/mol) values significantly correlate with the predicted inhibition constant  $pK_i$  ( $\mu\text{M}$ ) ( $r = 0.574$ ;  $p = 7.53 \times 10^{-20}$ ), as shown on the left graph. The 2D and 3D illustrations (Lines 2–5) show the interaction of celecoxib, apigenin,  $\beta$ -amyrin,  $\beta$ -eudesmol,  $\beta$ -sitosterol, daucosterol, farnesol, and myricetin with different amino acids of COX2.

### 3.4. Inhibition of COX2 Enzyme Activity In Vitro

To exemplarily verify the *in silico* predicted interaction of the compounds with COX2, we measured the enzymatic activity upon treatment with the selected seven phytochemicals. Figure 4A illustrates the rest activity of COX2 after treatment with  $\beta$ -sitosterol,  $\beta$ -amyrin,  $\beta$ -eudesmol, daucosterol, apigenin, myricetin, and farnesol at concentrations of 0.1 and 1  $\mu$ M.  $\beta$ -Sitosterol exerted the highest inhibitory effect on COX2, with percentages of 92% and 98%, respectively. By contrast, apigenin had the lowest inhibitory activity (42% and 90%, respectively). Then, we corrected the percentages of COX2 rest activity upon treatment with 0.1  $\mu$ M of the compounds *in vitro* with the LBE values *in silico* and found a significant correlation (Pearson correlation test,  $p = 0.030$ ;  $r = 0.736$ ) (Figure 4B). We also observed a significant correlation upon treatment with 1  $\mu$ M ( $p = 0.042$ ;  $r = 0.692$ ) (Figure 4C).

**Figure 4.** (A). The percentage of the rest activity of COX2 after treatment with apigenin,  $\beta$ -amyrin,  $\beta$ -eudesmol,  $\beta$ -sitosterol, daucosterol, farnesol, and myricetin at 0.1 and 1  $\mu$ M. (B,C). Pearson correlation of COX2 rest activity (%) at 0.1 and 1  $\mu$ M treatment, respectively, vs. low binding energy (kcal/mol). Blue points represent COX2 activity *in vitro* vs. lowest binding energy (LBE *in silico*). Red line represents linear regression of blue points.

### 3.5. Cytotoxicity against Tumor Cells In Vitro

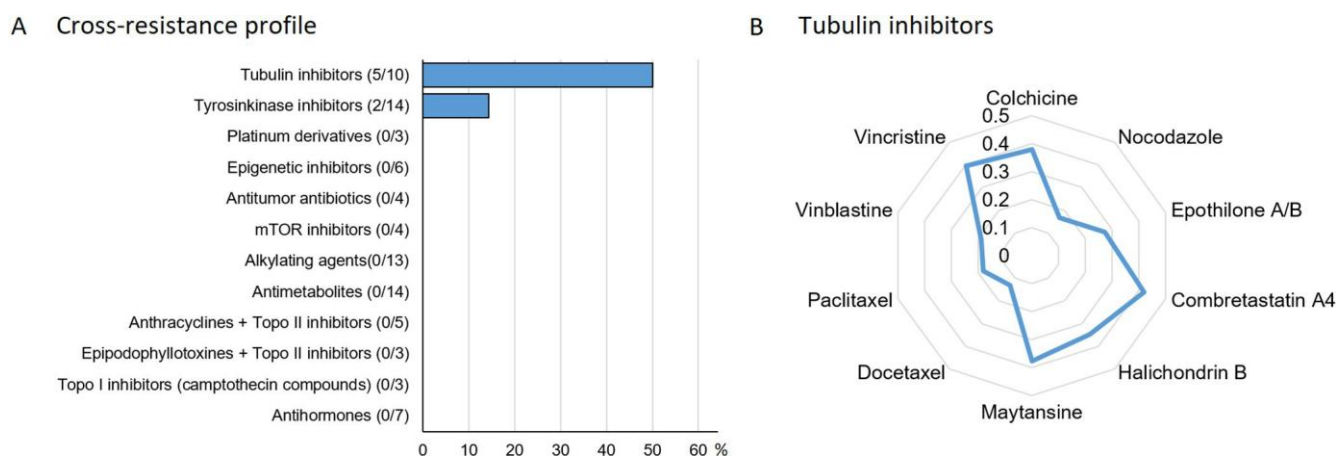

Since there is a mechanistic link between inflammation and carcinogenesis [52], we were interested in exploring the COX2-inhibitory activity of the selected compounds. The cytotoxicity of the selected compounds towards 60 cell lines of different tumor origins (leukemia, melanoma, brain tumors, carcinoma of the colon, ovary, breast, kidney, lung, or prostate) determined by a sulforhodamine B assay was mined in the NCI database ([dtp.cancer.gov](http://dtp.cancer.gov); accessed on 1 July 2023). The responsiveness of these cell lines is plotted as mean  $\log_{10}IC_{50}$  values for each tumor type in Figure 5.  $\beta$ -Sitosterol and daucosterol were minimally active against the tumor cell lines, while apigenin, myricetin, and farnesol were most active (Figure 5A). Celecoxib, the control drug, was the most active.  $\beta$ -Amyrin was not included in the NCI database. Therefore, we detected the cytotoxicity of this compound in CCRF-CEM cells which are also included in the NCI cell line panel and found that this compound did not affect these tumor cells. Since we previously investigated apigenin and farnesol in the NCI cell line panel [53–56], we focused on myricetin in the present study. The inhibitory activity of myricetin against the tumor cells shown in Figure 5B demonstrated that this compound was most active against colon and lung cancer cell lines. For comparison, celecoxib as a control drug was most active against leukemia and prostate cancer cell lines (Figure 5C).

**Figure 5.** (A) Cytotoxicity of the six selected chamomile derivatives with celecoxib (positive control) to 60 NCI tumor cell lines was plotted as mean log<sub>10</sub>IC<sub>50</sub> values for each tumor type. (B,C) the inhibitory activity of myricetin and celecoxib (control drugs), respectively, against the NCI 60 cell line panel plotted as mean log<sub>10</sub>IC<sub>50</sub>.

### 3.6. Oncobiogram Analysis

It is well accepted that natural products usually exert their bioactivity through multiple rather than single mechanisms [57]. Therefore, we assumed that myricetin might not only exert COX2-inhibitory activity. For this reason, we correlated the log<sub>10</sub>IC<sub>50</sub> values for myricetin in 60 tumor cell lines to those of 91 standard anticancer compounds from diverse pharmacological classes. Significant correlations in cellular responsiveness were observed between myricetin and five of the ten tubulin inhibitors and two of the fourteen tyrosine kinase inhibitors. Correlations with drugs of other classes were not found (Figure 6A). A closer look at which tubulin inhibitor is correlated to myricetin is shown in Figure 6B.

**Figure 6.** Cross-resistance profiling of myricetin to standard anticancer drugs. (A) Percentage of standard anticancer drugs from different pharmacological classes that significantly correlated to the responsiveness of NCI tumor cell lines to myricetin. It shows that 5 of the 10 tubulin inhibitors and 2 of the 14 tyrosine kinase inhibitors significantly correlate to myricetin. (B) The tubulin inhibitors are correlated to myricetin.

### 3.7. Effect of Myricetin on α-Tubulin

To validate the results obtained from the oncobiogram analysis that myricetin might interact with tubulin, U2OS cells transfected with GFP α-tubulin were subjected to myricetin treatment at concentrations of 0.1, 1, and 10 μM for 24 h. The effect of myricetin on microtubules is depicted in Figure 7. Indeed, myricetin inhibits microtubules. In contrast to the

well-organized microtubules seen in the untreated control cells, the myricetin-treated cells displayed shortened microtubule fragments that condensed around the nucleus, similar to vincristine-treated cells. Conversely, paclitaxel-treated cells exhibited extended and disorganized tubulin. Additionally, at the higher concentration of 10  $\mu\text{M}$  myricetin, not only was the polymerization of microtubules significantly hindered (as evident from the reduced density of microtubules), but there were also multiple spindle poles observed in the area of the nucleus.

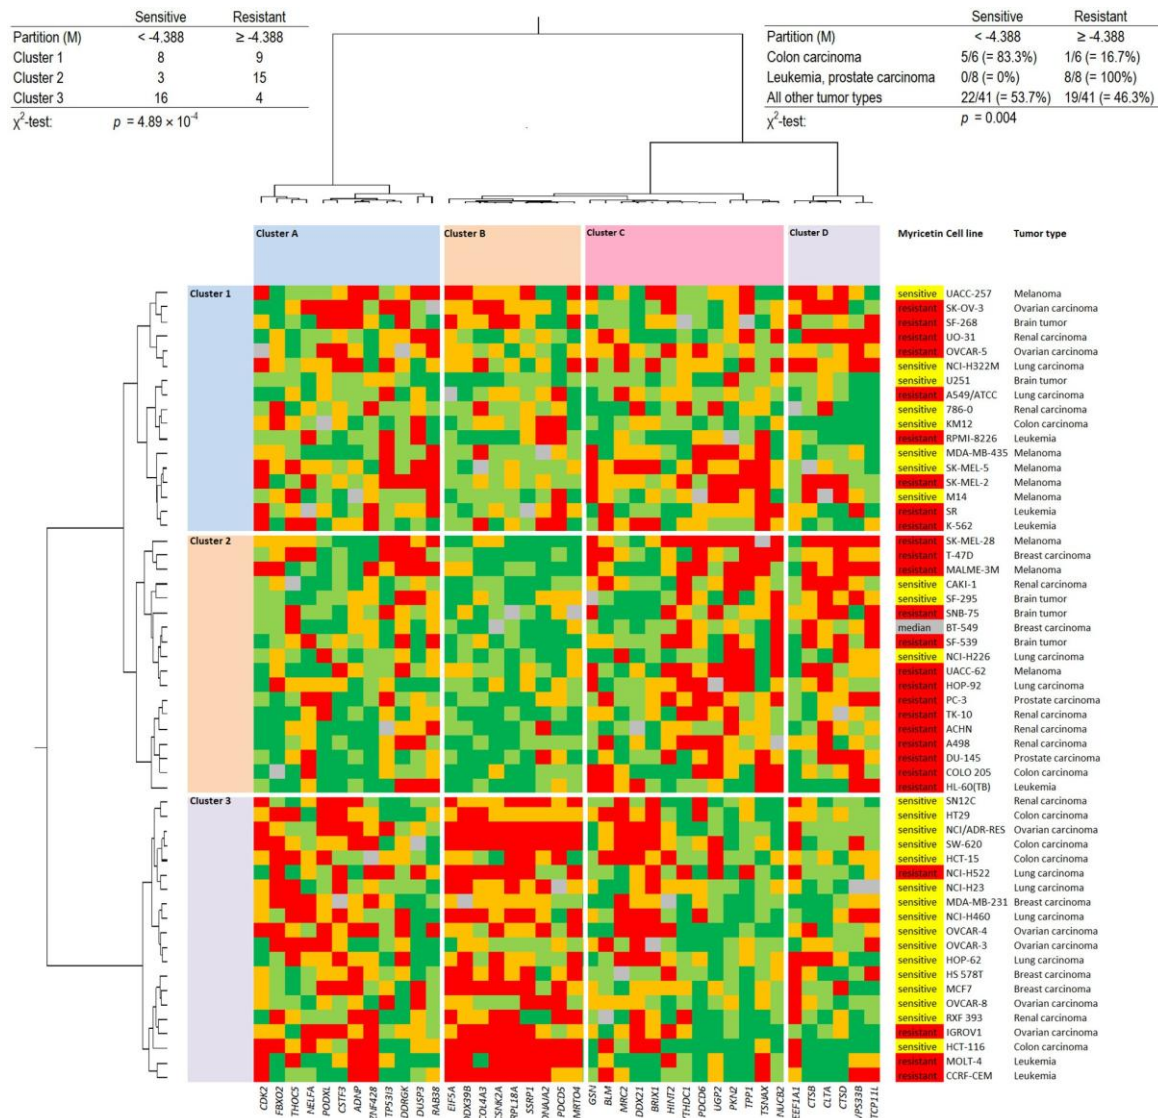

**Figure 7.** Disruption of the microtubule network in U2OS cells treated with myricetin. Fixed U2OS cells were treated with DMSO and various concentrations of Myricetin at 0.1, 1, 10  $\mu\text{M}$ , vincristine at 1  $\mu\text{M}$ , and paclitaxel at 1  $\mu\text{M}$  for 24 h. Micrographs of the cells were captured at  $63 \times 1.40 \text{ NA}$  objective (HC PL APO CS2  $63 \times / 1.40 \text{ OIL UV}$ ) magnification using the Thunder Imager Live Cell microscope. The microtubules were visualized with green fluorescence, and the images were merged with DAPI (blue) to represent the nucleus. Scale bars indicate 10  $\mu\text{m}$ .

### 3.8. Proteome Analysis

To gain more insight into the determinants that define the sensitivity or resistance of cell lines to myricetin, the expression of a total of 3171 proteins in the 60 NCI cell lines deposited at the NCI database ([ntp.cancer.gov](http://ntp.cancer.gov) accessed on 23 July 2023) was correlated to the  $\log_{10}\text{IC}_{50}$  values of myricetin using COMPARE analysis. A compilation of the top 40 proteins (20 directly correlating and 20 inversely correlating with myricetin) and their biological functions is compiled in Supplementary Table S2.

As a next step, we clustered the expression profiles using the hierarchical Ward cluster method within the first dimension and the  $\log_{10}\text{IC}_{50}$  values for myricetin in the second dimension. This two-dimensional clustering generated a color-coded heat map (Figure 8). Four major clusters were obtained for the 40 proteins (clusters A–D), and another three

clusters appeared for the tumor cell lines tested (clusters 1–3). The cellular responsiveness of the cell lines to myricetin was categorized by defining the cell lines as being sensitive if their individual  $\log_{10}IC_{50}$  values were smaller than the median value across all cell lines and as being resistant if the individual  $\log_{10}IC_{50}$  value was higher than the median. By using the  $\chi^2$  test, we calculated the statistical difference between the sensitive and resistant cell lines. Indeed, the distribution of clusters 1 and 2 (containing mainly myricetin-resistant cell lines) and cluster 3 (mainly containing sensitive cell lines) was statistically significant ( $p = 4.89 \times 10^{-4}$ ).

**Figure 8.** A 2D color-coded heat map and agglomerative cluster analysis of protein expression in the response of 60 NCI tumor cell lines to myricetin ( $\log_{10}IC_{50}$ ). On the right side of the heat map are the responsive cell lines to myricetin and their respective tumor types. Clusters A–D represent the 40 top proteins, and on the left are the 3 major clusters appearing for the tumor cell lines. The cellular responsiveness of various cell lines to myricetin was classified based on their individual  $\log_{10}IC_{50}$  values. Cell lines were classified as “sensitive” if their  $\log_{10}IC_{50}$  values were lower than the median value of all cell lines and as “resistant” if their  $\log_{10}IC_{50}$  values were higher than the median value. The  $\chi^2$  test shows statistical significance ( $p = 4.89 \times 10^{-4}$ ) by comparing the three different clusters of protein expression in the cell lines, where clusters 1 and 2 contained mainly myricetin-resistant cell lines, and cluster 3 contained mainly sensitive cell lines.

### 3.9. Drug Resistance Profiling of Myricetin

Moreover, we addressed the question of whether myricetin is involved in classical drug resistance phenotypes of ABC-transporters (P-glycoprotein, ABCB5, ABCC1, and ABCG2), as well as oncogenes (EGFR), tumor suppressors (TP53, WT1), and others (heat shock protein HSP90, glutathione S-transferase  $\pi$ , and the proliferation rate of the cell lines) (Table 2). We did not observe statistically significant correlations between the  $\log_{10}IC_{50}$  values for myricetin and any of the resistance parameters except for GSTP and cellular proliferation rates. This indicates that the effectiveness of myricetin may be limited by these two drug resistance mechanisms, while all other resistance mechanisms to established anticancer drugs may not be relevant for myricetin.

**Table 2.** Correlation between the  $\log_{10}IC_{50}$  values for myricetin and various mechanisms of multidrug resistance in the NCI panel of tumor cell lines, including ABC-transporter-mediated (P-glycoprotein/ABCB1, ABCB5, ABCC1, and ABCG2), EGFR, RAS, TP53, WT1, HSP90, GST, and the proliferative rate. Bold and \*  $p < 0.05$  and  $r > 0.3$  (or  $r < -0.3$ ).

### 3.10. Survival Analysis

Finally, we explored the relevance of COX2 expression for the survival prognosis of cancer patients. We speculated that a COX2 inhibitor (e.g., myricetin) should be more effective in tumors with high COX2 expression. A second assumption was that the connection between inflammation and COX2 expression is related to cancer growth, which might imply that high expression is related to short survival. Hence, COX2 inhibitors might contribute to the prolongation of the survival prognosis. Therefore, we performed Kaplan–Meier survival analyses using the KMPlotter database. The analysis of 21 tumor types revealed that high COX2 mRNA expression significantly correlated with shorter overall survival times in patients suffering from renal clear cell carcinoma than low COX2 expression (Figure 9A;  $p = 1.2 \times 10^{-4}$ ). Refining the analyses within this group of patients showed that female patients with renal clear cell carcinoma with high COX2 expression died significantly earlier than those with low COX2 expression (Figure 9B;  $p = 3 \times 10^{-5}$ ). Similarly, patients with low neoantigen load and high COX2 expression in their renal clear cell tumors had a worse survival prognosis than those with high COX2 expression (Figure 9C;  $p = 3 \times 10^{-5}$ ). This data indicates that COX2-inhibiting compounds from chamomile tea might exert beneficial effects in the prevention and treatment of this tumor type.

**Figure 9.** Kaplan–Meier statistics of overall survival time (months) for renal clear cell carcinoma correlating with the expression of *COX2* mRNA obtained from the KMPlotter database. **(A)** All patient profiles: *COX2* mRNA expression correlates significantly with overall survival time,  $p = 1.2 \times 10^{-4}$ . **(B)** Female patients’ profile: *COX2* mRNA expression correlates significantly with overall survival time,  $p = 3 \times 10^{-5}$ . **(C)** Patients with low neoantigen load and high *COX2* expression in their renal clear cell tumors had a worse survival prognosis than those with high *COX2* expression,  $p = 3 \times 10^{-5}$ .

#### 4. Discussion

Chamomile tea has been widely utilized as a spice for food preservation and in traditional medicine. Its phenolic and flavonoid attributes offer anti-inflammatory and antioxidant properties [58]. Extensive research has been conducted on the cellular and molecular mechanisms of chamomile tea constituents against cancer, such as apigenin [59]. Since inflammation is related to carcinogenesis [60], we focused this study on the phytochemical constituents of chamomile tea and their effects against *COX2*, as well as their anti-inflammatory and cytotoxic activities on cancer cells.

In understanding the beneficial effect, phytochemistry plays a crucial role in characterizing the composition of secondary plant metabolites [61]. In chamomile tea, more than 200 substances have been identified from the classes of flavonoids, terpenoids, alkaloids, tannins, and polyphenols [62]. Other teas also contain compounds of these chemical classes, with differences in the specific types and quantities of their substances. For example, chamomile tea does not contain caffeine, while black, green, pu-erh, and oolong teas contain varying high amounts of caffeine [63]. Catechin is found in a very high quantity in green tea due to its minimized antioxidant capacity compared to chamomile, black, and peppermint tea [64,65], and chamomile tea is also the richest in apigenin in contrast to peppermint tea [66]. The question is whether or not the interaction between these different substances may be synergetic or additive. We suggest that the death of cancer cells is more probable if exposed to a combination of various substances in an additive manner rather than surrendering in a synergistic way, which means that the cell has an evolutionary mechanism predisposed to it. Moreover, the concept has been explored as to whether phytochemicals may act synergistically or additively as chemopreventive agents or if combined with cancer drugs for therapeutic intervention. This has been documented in several studies [67–69].

*COX2* is an enzyme that plays a major role in inflammation and carcinogenesis. Since it is produced only during inflammation to catalyze the conversion of arachidonic acid to different prostaglandins [70]. Furthermore, arachidonic acid derivatives, including endocannabinoids such as 2-arachidonyl-glycerol, are capable of selectively binding to *COX2* to undergo oxygenation and catalysis, resulting in the synthesis of hydroxyl-endoperoxide analogs. The prostaglandin H analog is then converted into glyceryl prostaglandins, including prostaglandin E2 and prostaglandin I2, which have anti-inflammatory and proliferative properties [71,72].

The positive feedback loop between COX2 expression and PGE2 production is involved in multiple cellular mechanisms and pathways, which, among other functions, can contribute to the promotion of tumor growth [73]. Hence, the development of COX2 inhibitors is crucial for treating both inflammation and cancer. Unlike traditional non-steroidal anti-inflammatory drugs (NSAIDs) that can have severe gastrointestinal side effects due to the suppression of COX1, COX2 selective inhibitors celecoxib, rofecoxib, and valdecoxib have fewer side effects. Nevertheless, it has been observed clinically that COXIBs can lead to cardiovascular toxicity [74]. Considering this, we investigated the potential of chamomile tea to inhibit COX2 and its cytotoxic effects against different cancer types. For that purpose, we conducted resazurin assays to measure the growth-inhibitory effects of chamomile extract against hematopoietic tumor cell lines (leukemia, multiple myeloma) and colon cancer cells. Hematopoietic cancer cells are frequently more sensitive to cytotoxic agents than solid cancer cells. This was also observed with our chamomile extract. We used two colon cancer cell lines: a p53 wildtype and a knockout line. The tumor suppressor p53 is not only a major driver of carcinogenesis if it is mutated but also causes resistance to anticancer drugs [75]. In previous investigations, we found that HCT116 p53<sup>-/-</sup> cells were resistant to the standard anticancer drug doxorubicin [76]. The p53 knockout cells were also moderately but significantly resistant to the chamomile extract compared to p53 wildtype cells (2.65-fold).

We have also performed virtual screening and molecular docking. By calculating the lowest binding energies of more than 200 compounds, we were able to focus on a few promising molecules to conduct a COX2 inhibitor screening assay for testing their activity against COX2. Subsequently, we narrowed our focus on myricetin to study its effect against cancer in addition to inflammation by conducting multiple advanced analyses such as oncobiogram, proteome, and Kaplan–Meier survival analyses.

Our results from molecular docking and the COX2 inhibition screening assay were significantly correlative. Seven of our compounds ( $\beta$ -sitosterol,  $\beta$ -amyrin, dausterol,  $\beta$ -eudesmol, apigenin, farnesol, and myricetin) demonstrated high affinity binding to COX2. Moreover, the 60 NCI analyses have shown that  $\beta$ -sitosterol,  $\beta$ -eudesmol, and daucosterol were less effective on cancer cells compared to apigenin, myricetin, and farnesol. As we previously worked on apigenin and farnesol [55,56], we turned our focus to myricetin in the present investigation. The latter compound was more active against colon and lung cancer than other tumor types. This correlated with previous studies revealing that colon and lung cancers, among other tumor types, exhibited excessive COX2 expression [77,78]. More importantly, cell proliferation and anti-apoptosis effects were activated in colon cancer by the binding of prostaglandin E2 to its corresponding prostaglandin E2 receptor and to its respective G-protein, which stimulated the release of epidermal growth receptor (EGFR) responsible for the activation of extracellular kinase ERK and the AKT/PI3kinase pathway, and in lung cancer, the PGE2-EP1R-Gq complex triggered cell growth through the activation of phospholipase C and ERK [79].

An important aspect is that the expression of target proteins such as COX2 may not be of equal prognostic value in all cancer types. We mined the KM Plotter database to associate COX2 expression with survival times in various tumor types. This approach was recently also applied to antioxidant response genes and tumor suppressor genes [48,80].

High COX2 expression was significantly associated with a shorter survival probability in renal clear cell carcinoma patients, indicating that COX2 inhibition by myricetin might positively affect the survival times for patients suffering from this tumor type. Here, we found that high COX2 expression in renal clear cell carcinoma was associated with shorter overall survival times for patients, and female patients with high COX2 expression died significantly earlier than those with low COX2 expression. Moreover, patients with a low neoantigen load and high COX2 expression had a worse survival prognosis than those with high COX2 expression. It can be speculated that patients with low neoantigen loads might be less susceptible to immunotherapy approaches than those with high neoantigen loads and, thus, might be more immunotherapy-resistant [47].

Our findings suggest that targeting COX2 expression with compounds such as myricetin could be a promising strategy for improving the survival prognosis of patients with renal clear cell carcinoma, especially tumors with low neoantigen loads. It may be hypothesized that myricetin might be effective in this subgroup of patients.

Furthermore, we also found from the onco-biogram analysis that myricetin may also inhibit tubulin and tyrosine kinases. Substantially, this finding has been reinforced with our obtained data from immunofluorescence microscopy of the effect of myricetin on  $\alpha$ -tubulin. Myricetin at concentrations of 0.1 and 1  $\mu$ M has blocked microtubule polymerization in a comparable manner as vincristine at 1  $\mu$ M. Microtubules are composed of tubulin. They are responsible for the maintenance and stabilization of endothelial cells. The discovery of novel tubulin inhibitors plays an important role in tumor vasculature-based therapies [81]. Hence, the inhibition of tubulin by myricetin may not only be linked to the inhibition of COX2 but also to the inhibition of endothelial cell responses. Interestingly, many authors suggested that COX2 and PGE2 may work together to activate receptor tyrosine kinases, which are involved in regulating cell growth and division, e.g., in colon cancer [82,83]. In addition, COX2 overexpression in cancer cells elevated PGE2 production, which in turn activated vascular endothelial growth factor (VEGF) and/or other endothelial cell responses, promoting angiogenesis [73,79,84].

Additionally, in our analysis, we found that myricetin is not related to classical anticancer drug resistance mechanisms such as ATP-binding cassette (ABC) transporters (P-glycoprotein/ABCB1, ABCB5, ABCC1, ABCG2), tumor suppressors (TP53, WT1), or oncogenes (EGFR, RAS), except for glutathione S-transferase P (GSTP) and cellular proliferation rates.

COX2 overexpression contributed to P-glycoprotein-mediated multidrug resistance via regulation of c-Jun N-terminal protein kinase (JNK), which phosphorylates the transcription factor c-Jun on its N-terminus at Ser63/73 (pc-Jun) in colorectal cancer [85]. This could be an explanation for the absence of cross-resistance of P-glycoprotein-expressing cells towards myricetin.

WT1 is a tumor suppressor that produces different transcription factors that promote cell growth and survival. While its mutation has been initially linked to childhood kidney cancer (Wilms tumor), studies have suggested that WT1 can play either a promoting or inhibitory role in tumor formation and apoptosis in many tumor types [86–88]. A combined therapy targeting COX2 and WT1 has been proposed, as the two pathways have been shown to synergistically promote tumor cell proliferation in lung cancer. The authors found that suppressing the COX2 pathway with celecoxib increased WT1 expression, which may explain why myricetin did not appear to affect cross-resistance in WT1-expressing tumors [89]. Knocking down the WT1 gene led to an upregulation of COX2, particularly in Wilms' tumors, suggesting that inhibiting COX2 in combination with other targeted treatments could be beneficial in treating cancer [90,91]. P53 is also a tumor suppressor that regulates cell growth and promotes apoptosis (controlling cell cycle arrest) but, in parallel, also plays a crucial role in the progression of many cancer types when it is mutated. The *TP53* gene is mutated in several cancer types, including lung and colon cancer, and regaining its functions is an important therapeutic approach in cancer [92–94]. Genotoxic stress-induced p53 activated the Ras/Raf/MAPK pathway that led to COX2 expression downstream [95]. Moreover, COX2 promoted tumorigenesis by inhibiting the transcriptional activity of normal functional p53 and DNA damage-induced apoptosis. Further, The COX2-inhibitor NS-398 blocked the interaction between COX2 and p53, which activated apoptosis [96]. It has been discussed that the crosstalk between COX2 and p53 happens through different pathways [97].

There is a lot of published evidence that mutant p53 contributes to multidrug resistance [94]. It has been proposed to reduce drug resistance by increasing wild-type p53 in cancer. Myricetin increases the expression of the p53 protein and alters the function of Bcl-2 proteins, resulting in increased activity of apoptotic pathways such as Bax and Bak, which are also regulated by p53 [98]. This finding is particularly relevant because previous

investigations showed that the PGE2 ligand–receptor complex induced by COX2 inhibited the activation of Bax [99]. Consequently, we hypothesize that the crosstalk between p53 and COX2 and the COX2 inhibition by myricetin may explain why p53-mutant cells were not cross-resistant to myricetin. Nevertheless, we also found HCT116p53<sup>-/-</sup> cells were resistant to our chamomile extract compared to HCT116p53<sup>+/+</sup> cells. An explanation could be that other compounds, but not myricetin, in the chamomile extract were responsible for the resistance.

The epidermal growth factor receptor (EGFR) is a key factor in cell growth and is highly expressed in various carcinoma types, with lung and colon cancers being among the most affected. The activation of EGFR is essential for many cancer pathways, making it a prime target for cancer therapy. Despite the effectiveness of EGFR tyrosine kinase inhibitors in lung cancer treatment, resistance often develops through the activation of alternative pathways such as c-Met, HGF, and AXL, as well as divergent downstream pathways such as Ras/Raf/MAPK, Akt, and STAT. The Ras family, which includes H-Ras, N-Ras, and K-Ras, is one of the earliest discovered oncogenes and plays a crucial role in cell growth and proliferation by binding to the Raf and MAPK pathways controlled by EGFR. Mutations in Ras confer resistance to cancer drugs, making them a challenge in cancer therapy [100–103]. It is now well known that Ras mutant tumors are inherently resistant to anticancer agents, necessitating the development of alternative treatment strategies, and several agents targeting signaling components in the MAPK and PI3K pathways downstream of mutant K-Ras are currently undergoing clinical trials [104].

Myricetin has been reported to interact with and alter pathways such as AKT [105–108], which are linked to COX2. Myricetin-mediated COX2 inhibition might block EGFR- and Ras-related signaling cascades, potentially making tumor cells more sensitive to drugs and more susceptible to the blockade of cancer cell survival.

In the NCI cell line panel, there was no cross-resistance of myricetin to epirubicin, maytansine, vinblastine, pancratistatin (ABC transporters control drugs), erlotinib (EGFR inhibitor), melphalan (Ras control drug), 5-fluorouracil (p53 control drug), or ifosfamide (WT1 control drug). Nevertheless, there was a significant correlation with etoposide, which was used as the control drug for GSTP1. This is an enzyme mostly known for its detoxification, cytoprotective, and anti-apoptotic activities [109]. In aberrant crypt foci (ACF) in colonic adenoma, COX2 was inactive and GSTP1 was active, allowing ACF proliferation. ACF were also resistant to deoxycholic acid-induced apoptosis through this detoxification process rather than inflammation [110]. The activity of plant polyphenols and flavonoids against both GSTP1-1 and CS-X pumps on breast cancer cell lines has been investigated. Due to its multiple hydroxyl groups, myricetin had no inhibitory effect on GSTP1-1 and only a moderate effect on CS-X compared to two strongly active flavonoids, quercetin and luteolin [111]. GSTP1 plays an active role in cancer and contributes to drug resistance through its detoxification capability, and myricetin does not affect the function of GSTP1, which may explain the missing cross-resistance of GSTP1 to myricetin in the NCI cell line panel.

The main concept of our research efforts is to find cytotoxic compounds that can be used as functional food ingredients with negative side effects and that are able to bypass multidrug resistance or even provoke collateral sensitivity in resistant tumor cells [112–115]. Myricetin is a flavonoid present in tea, wine, fruits, and vegetables [116]. For decades, myricetin has been recognized for its antioxidant, anticancer, antidiabetic, and anti-inflammatory activities [117–120]. Furthermore, it has been reported that myricetin reduces resistance to anticancer drugs and other cytotoxic agents. Among them were camptothecin and podophyllotoxin by inducing topoisomerase I/II-DNA complex, cisplatin in ovarian and colon cancer cells by inducing apoptosis through Bax/Bcl-2 proteins, resveratrol in an additive manner by inhibiting 12-*O*-tetradecanoylphorbol-13-acetate (TPA) and EGF, as well as vincristine by blocking ABCC1 (MRP1) and ABCC2 (MRP2) [98,119,121,122].

There are findings that suggest that exposure to carcinogens may not only initiate carcinogenesis but also confer resistance to the very agents used to treat tumors [123–126].

Moreover, inflammation plays a significant role in the process of carcinogenesis, particularly in prostate and colon cancer. It is common sense that chronic inflammation leads to DNA damage, tissue damage, and abnormal cell growth that can ultimately result in cancer. Chemoprevention is a promising approach to preventing cancer by using natural or synthetic compounds to inhibit the development of cancer at its earliest stages. Several studies have demonstrated that anti-inflammatory agents prevent the initiation, promotion, and progression of cancer by modulating various molecular targets. Therefore, targeting inflammation through chemoprevention may represent a promising strategy for preventing cancer development and progression [127–131].

Therefore, it is straightforward to elaborate on chamomile, which contains not only myricetin but also various other bioactive compounds, including apigenin, farnesol, quercetin, and luteolin, to act as chemopreventive agents. This notion was supported by our growth inhibition assay, where the chamomile extract demonstrated significant activity against several cancer cell lines. It could, thus, be hypothesized that chamomile tea may help to prevent cancer and also suppress cancer cell growth at the early stages of tumor development.

For this reason, we used proteome analysis to gain more insights into the molecular mechanisms underlying the sensitivity and resistance of cancer cell lines to myricetin. The expression of 3171 proteins was determined in the NCI cell line panel [42] and correlated with the  $\log_{10}IC_{50}$  values of these cell lines for myricetin in the present investigation. The top 20 directly correlating proteins (indicating myricetin resistance) and the top 20 inversely correlating proteins (indicating myricetin sensitivity) were subjected to hierarchical cluster analysis. The distribution of the myricetin-resistant cell lines in clusters 1 and 2 and the myricetin-sensitive cell lines in cluster 3 was statistically significant ( $p = 0.00049$ ). The 40 relevant proteins associated with cellular myricetin responsiveness are involved in a variety of multifactorial interactions.

The formation of clusters A–D has been performed to better illustrate the distribution of protein expression in clusters 1–4 (i.e., red and green fields). The assembly of proteins in clusters A–D occurred according to their degrees of protein up- or downregulation in the specific tumor cell lines. A preferential assembly of the molecular and cellular functions of these proteins was not observed in clusters A–D. However, many proteins with functions relevant to cancer were identified from this proteomic analysis (Supplementary Table S2), e.g., proteins involved in mRNA metabolism (DDX39B, CSNK2A, RPL18A, MRT04, DDX21, BRIX1, HINT2, YTHDC1, and EEF1A1), proteins involved in programmed cell death (TP53I3, DDRGK, EIF5A, PDCD5, and PDCD6), proteins involved in cell growth, differentiation, and genome stability (CDK2, NELFA, PODXL, PKN2, THOC5, and BLM), transcription factors and signal transduction proteins (ADNP, ZNF428, SSRP1, TSNA, DUSPP3, RAB38, and TCP1), and others (FBO2, COL4A3, DNAJA2, GSN, MRC2, UGP2, TPP1, NUCB2, CTSB, CLTA, CTSD, and VPS33B). The exact mechanisms by which these proteins influence sensitivity or resistance to myricetin are largely unknown at present but deserve further investigation in the future. Clearly, the sensitivity and resistance of cancer cells to myricetin are multi-factorially determined. The identified proteins might be used to predict, prior to treatment, the responsiveness of cancer cells to myricetin and could guide the development of new therapeutic strategies for individualized cancer treatment.

These results are in agreement with a multitude of previous observations that natural products rather act by multiple mechanisms than by single mechanisms [57]. Additionally, the pharmacological effects of phytotherapeutics may result from synergetic interactions among multiple phytochemicals. Therefore, it is important to better understand the synergetic effects of herbal mixtures to develop more effective multi-target drugs with fewer side effects [132]. The generation of expression profiles to predict the response to chemotherapy is an important step toward individualizing chemotherapy [133,134]. In this context, the role of natural products cannot be ignored. If the profiles of standard drugs are known, then we could look for phytochemicals with fundamentally different expression profiles. This could provide a rational basis to make resistant and refractory tumors responsive to therapy again [135–137]. In the past, we have mainly used transcriptomics and

epigenomics [138–143]. The significance of such profiles for cancer prevention with tea is also worth noting, as it has a different profile than cytostatic drugs. Overall, the use of expression profiles from natural products offers promising avenues for improving cancer treatment and prevention.

## 5. Conclusions

In conclusion, the effects of tea on cancer prevention and therapy are not solely attributed to apigenin, as previously reported [144–146], but to a combination of many other natural substances. In the present work, we focused particularly on myricetin due to its potential cancer-inhibiting bioactivity. However, the inhibitory effect of myricetin on cancer cells may be moderate and weaker than conventional anticancer drugs, making it more appropriate for cancer prevention than therapy. Nonetheless, the potential of myricetin and other natural substances in cancer prevention and treatment cannot be ignored. Therefore, our findings provide valuable insights into the potential of natural substances for cancer prevention and as an additive to cancer therapy. Ultimately, the development of effective cancer prevention strategies is critical to reducing the burden of this disease on individual cancer patients. The potential of myricetin for individualized treatment is worth further exploring in the future.

**Abstract:** Background and aim: Chamomile tea, renowned for its exquisite taste, has been appreciated for centuries not only for its flavor but also for its myriad health benefits. In this study, we investigated the preventive potential of chamomile (*Matricaria chamomilla* L.) towards cancer by focusing on its anti-inflammatory activity. Methods and results: A virtual drug screening of 212 phytochemicals from chamomile revealed  $\beta$ -amyryn,  $\beta$ -eudesmol,  $\beta$ -sitosterol, apigenin, daucosterol, and myricetin as potent NF- $\kappa$ B inhibitors. The in silico results were verified through microscale thermophoresis, reporter cell line experiments, and flow cytometric determination of reactive oxygen species and mitochondrial membrane potential. An oncobiogram generated through comparison of 91 anticancer agents with known modes of action using the NCI tumor cell line panel revealed significant relationships of cytotoxic chamomile compounds, lupeol, and quercetin to microtubule inhibitors. This hypothesis was verified by confocal microscopy using  $\alpha$ -tubulin-GFP-transfected U2OS cells and molecular docking of lupeol and quercetin to tubulins. Both compounds induced G2/M cell cycle arrest and necrosis rather than apoptosis. Interestingly, lupeol and quercetin were not involved in major mechanisms of resistance to established anticancer drugs (ABC transporters, *TP53*, or *EGFR*). Performing hierarchical cluster analyses of proteomic expression data of the NCI cell line panel identified two sets of 40 proteins determining sensitivity and resistance to lupeol and quercetin, further pointing to the multi-specific nature of chamomile compounds. Furthermore, lupeol, quercetin, and  $\beta$ -amyryn inhibited the mRNA expression of the proinflammatory cytokines *IL-1 $\beta$*  and *IL6* in NF- $\kappa$ B reporter cells (HEK-Blue Null1). Moreover, Kaplan–Meier-based survival analyses with NF- $\kappa$ B as the target protein of these compounds were performed by mining the TCGA-based KM-Plotter repository with 7489 cancer patients. Renal clear cell carcinomas (grade 3, low mutational rate, low neoantigen load) were significantly associated with shorter survival of patients, indicating that these subgroups of tumors might benefit from NF- $\kappa$ B inhibition by chamomile compounds. Conclusion: This study revealed the potential of chamomile, positioning it as a promising preventive agent against inflammation and cancer. Further research and clinical studies are recommended.

## 1. Introduction

It is well-known that inflammation can promote tumorigenesis [1]. Numerous clinical investigations have unraveled that precancerous disorders resulting from inflammation can be prevented from malignant progression by inhibiting inflammation [2]. Therefore, the

quest for novel, effective options to prevent inflammation-related carcinogenesis represents a major focus in oncological research.

In recent years, natural products have gained considerable interest because of their diverse chemical composition, good tolerability, and beneficial pharmacological properties. It has been repeatedly reported that a majority of the current anticancer drugs established in the clinic are of natural origin or derived from natural products [3–5]. Furthermore, advancements in analytical tools and bioinformatics (e.g., “-omics” technologies) have made it easier to harness the potential of natural compounds [3,6–8]. One of the most renowned examples is paclitaxel, extracted from the bark of the Pacific yew, *Taxus brevifolia* [9]. Another notable example is artemisinin, obtained from *Artemisia annua*, which exerts not only antimalarial but also anti-inflammatory and anticancer activities [10]. Similarly, chamomile represents another example of a valuable medicinal plant. It is not just a well-known and widely consumed beverage, as it also possesses pharmacological properties due to its rich content of phenols and flavonoids, which confer antioxidant, antiproliferative, anti-inflammatory, and potential anticancer effects [11–13]. Given the established connection between inflammation and the development of cancer, we focused on the anti-inflammatory properties of *Matricaria chamomilla*.

Previously, we analyzed the inhibitory effects of chamomile on cyclooxygenase-2 (COX2) [12]. Because COX2 expression is regulated by nuclear factor kappa B cells (NF- $\kappa$ B), we then shifted our focus to this transcription factor. COX2 and NF- $\kappa$ B are both well-known players in the inflammatory process. COX2 is an enzyme responsible for producing prostaglandins during inflammation [14]. Nuclear factor- $\kappa$ B is crucial for various cellular processes including inflammation, immunity, cell growth, differentiation, and apoptosis [15]. The NF- $\kappa$ B pathway is generally a proinflammatory signaling pathway by promoting the expression of proinflammatory genes, such as cytokines, chemokines, and adhesion molecules [16]. It is activated through the conversion of the I $\kappa$ B kinase complex (IKK) into a catalytic active form, leading to the degradation of the I $\kappa$ B–NF- $\kappa$ B complex, which releases NF- $\kappa$ B into the nucleus [17]. In chronic inflammation and cancer, NF- $\kappa$ B is persistently dysregulated and active, and it has been implicated in the promotion of cell growth, angiogenesis, and cell proliferation [18]. This underscores the importance of the discovery and development of drugs targeting NF- $\kappa$ B and its pathways.

Thus, our aim in this study was to investigate the inhibitory activity of the secondary metabolites of chamomile (*Matricaria chamomilla* L.) against NF- $\kappa$ B. Through in silico screening, we have determined 6 out of 212 chamomile compounds based on their binding energy (kcal/mol) by using bioinformatical compound screening with PyRx and molecular docking with AutoDock4.2.6. Given our prior research on apigenin [19,20], we now directed our focus towards  $\beta$ -amyryn. The inhibitory activity against NF- $\kappa$ B was evaluated using microscale thermophoresis, an NF- $\kappa$ B reporter cell assay, as well as flow cytometric measurements of reactive oxygen species and mitochondrial membrane potential.

In the second part of our analyses, we selected the cytotoxic compounds lupeol and quercetin from *M. chamomilla*. Using oncobiogram analyses with the NCI panel of tumor cell lines and subsequent verification through confocal microscopy with  $\alpha$ -tubulin-GF- transfected U2OS cells, we found that both compounds inhibited microtubules and induced G2/M cell cycle arrest. To perform hierarchical cluster analyses of the proteomes of 60 NCI cell lines, we generated a bioactivity oncobiogram. As lupeol and quercetin were not involved in classical drug resistance mechanisms (e.g., ABC transporters, TP53, EGFR), hierarchical cluster analyses using proteomic expression data of 3171 proteins in the NCI tumor cell line panel identified candidate proteins predicting sensitivity or resistance to these two compounds.

Moreover, Kaplan–Meier-based survival analyses with NF- $\kappa$ B as the target protein of these compounds were performed by mining the TCGA-based KM-Plotter repository with 7489 cancer patients to envision which tumor types and subtypes might benefit from chamomile treatment.

## 2. Materials and Methods

### 2.1. Phytochemical Analysis, Virtual Drug Screening, and Molecular Docking

Phytochemical analysis through liquid chromatography–diode array detector–quadrupole time-of-flight mass spectrometry (LC-DAD-QToF) was previously reported by us [12]. Virtual drug screening of more than 1000 chamomile compounds to COX2 has been also reported by us [12]. This repository of compounds was used for virtual screening and molecular docking to NF- $\kappa$ B in the present investigation.

The crystal structure of NF- $\kappa$ B was taken from the Protein Data Bank (PDB: 1NFI) [21,22], and only the homodimer structure of NF- $\kappa$ B p65-RelA was prepared for virtual drug screening using the software ChimeraXV5 (University of California in San Francisco, San Francisco, CA, USA) (accessed on 30 March 2023) [23]. The water molecules were deleted, polar hydrogen atoms were added and merged, the missing atoms and bonds were repaired, and Kollman charges were added. More than 1000 chamomile compounds were then screened for binding to NF- $\kappa$ B p65-RelA using PyRx version 0.8 [24,25]. Afterwards, 212 out of the 1000 ligands were selected based on their lowest binding energy (LBE, kcal/mol) and subjected to molecular docking against NF- $\kappa$ B using AutoDock 4.2.6 [26–28]. The DNA active site situated in the Rel homology domain (RHD) of NF- $\kappa$ B was defined for the grid box [17,21,29]. Its dimensions were 38 × 58 × 82 Å spacing, 0.622 Å at the grid-center, x = −4.515 Å, y = 72.657 Å, and z = 100.06 Å. The Lamarckian Genetic Algorithm (LGA) was applied to seek the lowest binding energies (LBE, kcal/mol) and predicted inhibition constants (pKi,  $\mu$ M) with docking parameters set to 250 runs and 2,500,000 energy evaluations for each cycle. The data from the histogram were organized in an Excel table (Microsoft Excel 2021 (Version 2306, Build 16.0.16529.20164)). The mean values  $\pm$  SD were calculated from each of the three independent dockings. BIOVIA Discovery Studio Visualizer 2021 was used to generate the 3D visualization of interactions between the ligand and the amino acid residues of the crystal structure 1NFI [30].

### 2.2. Microscale Thermophoresis

The microscale thermophoresis (MST) technique was performed to validate the interaction between NF- $\kappa$ B (12054-H09E, Sino Biological Europe GmbH, Eschborn, Germany) and  $\beta$ -amyryn. The recombinant NF- $\kappa$ B protein was labeled using the Monolith Protein Labeling Kit RED-NHS 2nd Generation (MO-L011, NanoTemper Technologies GmbH, Munich, Germany) in accordance with the protocol provided by the manufacturer. Various concentrations (starting from 300  $\mu$ M to 30 nM) of  $\beta$ -amyryn were incubated with labeled NF- $\kappa$ B (at a concentration of 200 nM) (1:1) for 30 min at room temperature in the dark. The analysis was performed using standard capillaries in the Monolith NT.115 system (NanoTemper Technologies GmbH, Munich, Germany). The MST experiment was conducted with an LED power of 40% and an MST power of 10% for the labeled NF- $\kappa$ B. For the data analysis, the NanoTemper Analysis Software was utilized.

### 2.3. Cell Culture

The HEK-Blue Null1 cells are a subtype of human embryonic kidney cells (HEK 293) that express secreted embryonic alkaline phosphatase (SEAP) under the control of an NF- $\kappa$ B promoter. The cells were obtained from Invivogen (Toulouse, France) (<https://www.invivogen.com/hek-blue-null1v>, accessed on 5 December 2019). The cells were maintained in DMEM medium supplied with 2 mM of L-glutamine, 10% fetal bovine serum (FBS), 1% penicillin–streptomycin (Invitrogen, Darmstadt, Germany), and 1 mL of normocin (100  $\mu$ g/mL). After the second passage, Zeocin (100  $\mu$ g/mL) was then added to the media (Invivogen, Toulouse, France). The cells were cultured at 37 °C in a humidified environment with 5% CO<sub>2</sub> [31].

The drug-sensitive CCRF-CEM and multidrug-resistant P-glycoprotein-overexpressing CEM-ADR5000 leukemia cells were cultured in RPMI medium mixed with 1% penicillin/streptomycin and 10% FBS. Doxorubicin was added to CEM/ADR5000 every two weeks. The HCT116 p53<sup>+/+</sup> human wild-type colon cancer cells and their knockout p53<sup>-/-</sup>,

alongside the wild-type human glioblastoma U87.MG cells and their transfected cells with  $\Delta$ EGFR (U87.MG $\Delta$ EGFR), were all nurtured in DMEM medium mixed with 1% penicillin/streptomycin and 10% FBS. U87.MG $\Delta$ EGFR and HCT116 p53<sup>-/-</sup> were treated every two weeks with geneticin (400  $\mu$ g/mL).

#### 2.4. NF- $\kappa$ B Reporter Assay

The assay was performed according to the instructions of Invivogen (Toulouse, France). The HEK-Blue Null1 (HKBN1) cells were seeded in a 96-well plate at 100  $\mu$ L/well and 50,000 cells/well overnight. Then, cells were treated for 24 h with 0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M of  $\beta$ -amyryn,  $\beta$ -sitosterol,  $\beta$ -eudesmol, daucosterol, myricetin, and apigenin. Triptolide was used as the positive control at concentrations of 0.1  $\mu$ M and 1  $\mu$ M. DMSO served as a negative control. TNF- $\alpha$  (100 ng/mL) was added for 24 h to induce the activity of NF- $\kappa$ B. The incubation was at 37 °C in 5% CO<sub>2</sub>. QUANTI-Blue™ (QB) solution was used for the detection and quantification of NF- $\kappa$ B (Invivogen, Toulouse, France), and 180  $\mu$ L of QB was mixed with 20  $\mu$ L of the supernatant and then incubated for 15 min at 37 °C in 5% CO<sub>2</sub> [32]. The measurement was at 620–655 nm using a microplate reader (Tecan, Crailsheim, Germany). The experiment was independently repeated three times.

#### 2.5. Mitochondrial Membrane Potential Assay

The JC-1 mitochondrial membrane potential assay kit was purchased from Cayman Chemical (Distributor Biomol GmbH, Hamburg, Germany) [33] and used following their instructions [34]. Aliquots of 125,000 HBN1 cells/well and 2 mL/well were seeded in a 6-well plate and left overnight.  $\beta$ -Amyryn (10  $\mu$ M) and vinblastine as the positive control were added to the cells along with DMSO as the negative control for 24 h. The next day, 100 ng/mL of TNF- $\alpha$  were added for 3 h to induce the activation of NF- $\kappa$ B. The cells were then stained with prediluted JC-1 (1  $\mu$ L of JC-1 in 9  $\mu$ L of culture medium) and incubated at 37 °C for 15 min in the dark. Next, the cells were washed with cell-based assay buffer and centrifuged twice at 400  $\times$  g for 5 min. Finally, the samples were directly measured with a flow cytometer (Novocyte Quanteon, Agilent Technologies, Frankfurt, Germany). Samples of 20,000 cells were analyzed and separated depending on the fluorescence intensity. The JC-1 dye was activated using a 488 nm argon laser. The JC-1 aggregates and monomers both emit green fluorescence (measured at 527 nm), which is detected in the FL1 channel (set at 530 nm). However, JC-1 aggregates representing the healthy cells also emit red fluorescence (measured at 595 nm), detected in the FL2 channel (set at 590 nm) [35]. All experiments were performed three times. The FSC files were analyzed using FlowJo\_V10 Software (FLOWJO.LLC 1997–2018).

#### 2.6. ROS Detection

The HEK-Blue null1 cells were seeded in a 6-well plate and incubated for 24 h, allowing attachment. The treatment was for 24 h with varying concentrations of  $\beta$ -amyryn (0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M). The 3rd day, 100 ng/mL of TNF $\alpha$  was added and left for 24 h. The 4th day, the cells were harvested, washed, and suspended with 1 mL of PBS. 2'-Dichlorodihydrofluorescein diacetate (H<sub>2</sub>DCFH-DA, 10  $\mu$ M; Sigma-Aldrich, Taufkirchen, Germany) was added and incubated for 30 min at 37 °C. Cells were treated with H<sub>2</sub>O<sub>2</sub> (10  $\mu$ L of the stock concentration; Sigma-Aldrich) for 15 min to activate the ROS generation. DMSO plus H<sub>2</sub>O<sub>2</sub> plus TNF- $\alpha$ , cells plus H<sub>2</sub>O<sub>2</sub>, as well as cells without any treatment were used as controls. Lastly, the samples were directly assessed using a Novocyte Quanteon flow cytometer (Agilent Technologies). The analysis was performed with FlowJo Software (FLOWJO.LLC, 1997–2018). The procedure was independently conducted in triplicate, as described by us [36,37].

#### 2.7. Growth Inhibition Assays

The  $\beta$ -amyryn cytotoxicity was measured through the resazurin reduction assay at 7 different concentrations. Human CCRF-CEM leukemia cells were seeded at a density of

$1 \times 10^4$  cells/well and 100  $\mu\text{L}$ /well of RPMI 1640 medium in 96-well plates. The cytotoxicity of lupeol and quercetin (Sigma–Aldrich) was tested at 10  $\mu\text{M}$ , 25  $\mu\text{M}$ , 50  $\mu\text{M}$ , and 100  $\mu\text{M}$  on six different cell lines: CCRF-CEM, CEM/ADR5000, U87.MG, U87.MG/ $\Delta\text{EGFR}$ , HCT116 p53<sup>+/+</sup>, HCT116 p53<sup>-/-</sup>, and U2OS.

After 72 h of treatment with  $\beta$ -amyryn, lupeol, and quercetin, 20  $\mu\text{L}$  of 0.01% resazurin solution from Promega (Mannheim, Germany) was added to each well and incubated for over 4 h. The fluorescence signal was subsequently detected using an Infinite M2000 Pro-plate reader (Tecan) with an excitation wavelength of 544 nm and an emission wavelength of 590 nm. The experiment was performed independently in triplicate, and the concentrations were tested in sextuplicate. The results were interpreted as a percentage of cell viability and graphed as a dose–response curve. The  $\text{IC}_{50}$  value was calculated using Microsoft Excel 2021 (Version 2306, Build 16.0.16529.20164).

A range of human tumor cell lines with diverse origins, including leukemia, melanoma, brain tumors, and carcinoma of the lung, colon, kidney, ovary, breast, or prostate were employed by The National Cancer Institute’s Developmental Therapeutics Program (Bethesda, MA, USA) [38,39] to conduct drug screening. The  $\text{Log}_{10}\text{IC}_{50}$  values, obtained through a sulforhodamine 123 assay, along with transcriptomic and proteomic expression data, were deposited on the NCI website [40]. Statistical correlation analyses were performed using Pearson’s correlation test (WinStat, Kalmia Inc., Cambridge, MA, USA; accessed on 19 November 2023).

### 2.8. Immunofluorescence Microscopy of $\alpha$ -Tubulin

U2OS osteosarcoma cells were cultured in  $\mu$ -slide 8-well plates (ibidi, Gräfelfing, Germany) at a density of 30,000 cells per well and allowed to adhere for 24 h. Subsequently, the cells were treated with concentrations of 0.1, 1, and 10  $\mu\text{M}$  of  $\beta$ -amyryn, quercetin, and lupeol. As positive controls, paclitaxel (1  $\mu\text{M}$ ) and vincristine (1  $\mu\text{M}$ ) were used (obtained from the University Hospital Pharmacy, Mainz, Germany), while DMSO served as the negative control. After 24 h of treatment, the cells were rinsed with PBS, fixed with 4% paraformaldehyde, and stained with 1  $\mu\text{g}/\text{mL}$  of 4’6-diamidino-2-phenylindole (DAPI, Sigma Aldrich). Mounting medium (ibidi, Gräfelfing, Germany) was applied before imaging. Widefield imaging was conducted using a THUNDER Imager Live Cell (Leica Microsystems, Wetzlar, Germany) mounted on a Leica DMi8 microscope stand with a 63 $\times$ /1.40 NA objective (HC PL APO CS2 63 $\times$ /1.40 OIL UV). Fluorescence excitation was achieved using LED light sources at 395 nm for DAPI and 488 nm for tubulin–GFP. The camera (Leica DFC9000 GTC) operated in 2  $\times$  2 binning mode, resulting in a pixel size of 206 nm. Image analysis was performed using ImageJ 1.54f software (National Institute of Health, Bethesda, MD, USA). The experimental methodology and microscopy techniques have been previously described [12].

### 2.9. Molecular Interaction with $\alpha$ - and $\beta$ -Tubulins

In order to study the affinity of lupeol and quercetin with tubulins, molecular docking in the defined mode was performed with  $\alpha 1\text{B}$ ,  $\beta\text{I}$ , and  $\beta\text{IVb}$  microtubules (PDB ID: 5N5N). The C and H chains of 5N5N were selected for docking, and three grid boxes in three different binding sites of vincristine, paclitaxel, and colchicine were used to compare the binding affinity of the two compounds with their receptor. Their grid box dimensions were 76  $\times$  70  $\times$  60  $\text{\AA}$  spacing, 0.375  $\text{\AA}$  at the grid-center,  $x = 48.907 \text{\AA}$ ,  $y = 37.217 \text{\AA}$ , and  $z = 199.886 \text{\AA}$ , 54  $\times$  68  $\times$  42  $\text{\AA}$  spacing, 0.375  $\text{\AA}$  at the grid-center,  $x = 49.973 \text{\AA}$ ,  $y = 32.388 \text{\AA}$ , and  $z = 177.504 \text{\AA}$ , and 126  $\times$  100  $\times$  124  $\text{\AA}$  spacing, 0.242  $\text{\AA}$  at the grid-center,  $x = 52.555 \text{\AA}$ ,  $y = 44.736 \text{\AA}$ , and  $z = 169.256 \text{\AA}$ , respectively. The molecular docking was performed with AutoDock 4.2.6, and the 3D and 2D pictures showing the interaction of the amino acids with the protein tubulin 5N5N were made using BIOVIA Discovery Studio Visualizer 2021. The mean and SD values were calculated with Microsoft Excel 2021 (Version 2306, Build 16.0.16529.20164) from three independent dockings.

### 2.10. Cell Cycle Analysis

U2OS cells ( $250 \times 10^3$  cells/well) were seeded and treated for 72 h with a concentration of  $1 \times IC_{50}$  and  $4 \times IC_{50}$  of lupeol and quercetin, DMSO (negative control), and vincristine (positive control,  $1 \times IC_{50}$ ) (obtained from the University Hospital Pharmacy, Mainz, Germany). The cells were harvested and centrifuged with cold PBS twice (1500 rpm for 5 min). Cold ethanol (80%) was used for fixation. Samples were kept at  $-20^\circ\text{C}$  for 72 h. Before measurement, the cells were suspended with RNAs (Roche Diagnostics, Mannheim, Germany) and then incubated for 30 min. Lastly,  $50 \mu\text{g/mL}$  of propidium iodide (PI) (Sigma-Aldrich) was added before the measurement. The DNA histogram was generated using FL2-A/histogram properties. All experiments were repeated three times independently. The cell cycle distributions were analyzed using FlowJo software (version 10.8.1) (Celeza, Olten, Switzerland) [41,42].

### 2.11. Cell Death Detection

CCRF-CEM cells ( $1 \times 10^6$  cells/well) and U2OS cells ( $250 \times 10^3$  cells/well) were seeded and treated for 72 h with varying concentrations of lupeol and quercetin. The treatment concentrations for CCRF-CEM cells included  $1/4 \times IC_{50}$ ,  $1/2 \times IC_{50}$ ,  $1 \times IC_{50}$ ,  $2 \times IC_{50}$ , and  $4 \times IC_{50}$ . For U2OS cells, the treatment concentrations were  $1/2 \times IC_{50}$ ,  $1 \times IC_{50}$ ,  $2 \times IC_{50}$ , and  $4 \times IC_{50}$ . DMSO was used as a negative control. A fluorescein isothiocyanate (FITC)-conjugated annexin V/propidium iodide (PI) assay kit (Bio version Biotec, Heidelberg, Germany) was used to detect apoptosis. The cells were washed with cold PBS and then with  $1 \times$  binding buffer (Bio Version). Thereafter,  $52.5 \mu\text{L}$  of annexin V master mix ( $2.5 \mu\text{L}$  of annexin V,  $50 \mu\text{L}$  of  $1 \times$  binding buffer) was added to the cells and incubated at  $4^\circ\text{C}$  in the dark for 15 min. Finally,  $403 \mu\text{L}$  of PI master mix ( $3 \mu\text{L}$  of PI,  $400 \mu\text{L}$  of  $1 \times$  binding buffer) was added to the cells. The experiments were performed three times independently [41,42].

### 2.12. Western Blotting

The HEK-Blue null1 cells were seeded for 24 h at a density of 500,000/well in 6-well plates and then treated for 24 h with  $10 \mu\text{M}$  or  $50 \mu\text{M}$  of  $\beta$ -amyryn, quercetin, and lupeol. DMSO served as a negative control. The next day,  $100 \text{ ng/mL}$  of  $\text{TNF}\alpha$  was added and left for another 24 h. The cells were harvested on the 4th day, washed, and suspended with  $1 \text{ mL}$  of  $\text{PBS} \times 2$ . The total protein was extracted using Mammalian Protein Extraction Reagent (M-PER) containing 1% protease inhibitor and phosphatase inhibitor (Thermo Fisher Scientific, Darmstadt, Germany). The protein amounts were quantified using a microvolume spectrophotometer (NanoDrop, Thermo Fisher Scientific). Afterwards,  $30 \mu\text{g}$  of protein extracts was loaded into each channel of 10% SDS-PAGE gel. After the separation and transfer steps, the polyvinylidene difluoride membrane was blocked in a TBST buffer consisting of 5% bovine serum albumin for 2 h. The membrane was incubated in 1:1000 primary antibodies rabbit mAb NF- $\kappa\text{B}$  p65 and GAPDH overnight and in secondary antibody 1:2000 anti-rabbit IgG HRP-linked for 1 h 30 (Cell Signaling Technology, Leiden, The Netherlands). All experiments were repeated three times. The mean and SD values were calculated with Microsoft Excel 2021 (Version 2306, Build 16.0.16529.20164) from three independent dockings. The significance level  $p$  value was calculated using  $t$ -test tails 2, type2.

### 2.13. Quantitative Real-Time RT-PCR

The RNA was extracted from the HEK-Blue Null 1 cells treated with  $10 \mu\text{M}$  or  $50 \mu\text{M}$  of  $\beta$ -amyryn, quercetin, and lupeol (Sigma-Aldrich) for 24 h and  $100 \text{ ng/mL}$  of  $\text{TNF-}\alpha$  for 24 h. The extraction was performed with the RNeasy Kit from Qiagen (Hilden, Germany). The extracted RNA was converted to cDNA using Luna Script™ RT SuperMix Kit (E3010) following the instructions of the manufacturer (New England Biolabs GmbH, Frankfurt, Germany).

The primers for the *IL1B* and *IL6* genes (interleukin-1 $\beta$  and interleukin-6) were retrieved from the literature [43]. *GAPDH* primers were designed following the protocol previously reported by our team [44]. The primers were procured from Eurofins Genomics Germany GmbH (Ebersberg, Germany).

The real-time quantitative polymerase chain reaction (RT-qPCR) was carried out using 5 $\times$  Hot Start Taq EvaGreen<sup>®</sup> qPCR Mix (Axon-Labortechnik, Kaiserslautern, Germany) in a CFX384<sup>™</sup> Real Time PCR Detection System (Bio-Rad Laboratories GmbH, Feldkirchen, Germany). The expression of the genes was normalized to *GAPDH*, and the fold of change was calculated with the  $2^{\Delta\Delta C_t}$  method [45]. The experiments were independently repeated three times. The mean and SD values were calculated with Microsoft Excel 2021 (Version 2306, Build 16.0.16529.20164). The degree of significance was determined using the *t*-test tails 2 type 2 calculation method.

#### 2.14. Statistical Analysis

For hierarchical cluster analysis of proteomic expression data, we used the method of Ward implemented in the WINStat program (Kalmia, CA, USA).

For survival analysis, we applied Kaplan–Meier statistics. The KM-Plotter database contains data from over 7000 samples across 21 different tumor types [46]. To assess the prognostic significance of *NFKB2* mRNA expression for cancer patient survival, we employed Kaplan–Meier statistics. We utilized false discovery rate (FDR) calculations to mitigate type I errors in multiple comparisons [47,48]. Specifically, we considered only Kaplan–Meier statistics with FDR rates of 5% or lower [49].

### 3. Results

#### 3.1. Molecular Docking In Silico

Recently, we reported a chemical library of chamomile compounds [12]. In the present investigation, 212 chamomile compounds were utilized for molecular docking with the homodimer structure of NF- $\kappa$ B p65-RelA (PDB: 1NFI) by means of the AutoDock 4.2.6 program (Supplementary Table S1). Out of these 212 molecules, the top 28 were selected for further analysis. Table 1 shows their lowest binding energies (LBE, kcal/mol) as well as their predicted inhibition constants (pKi,  $\mu$ M).

The LBE and pKi values of these 28 compounds significantly correlated with each other using the Pearson correlation test ( $p = 2.61 \times 10^{-6}$ ;  $r = 0.76$ ; Figure 1A). Fifteen LBE values were below  $-6$  kcal/mol, with a range between  $-8.70 \pm <0.01$  kcal/mol for  $\beta$ -amyryn and  $-6.01 \pm 0.12$  kcal/mol for chlorogenic acid. Their pKi values ranged between  $0.42 \pm <0.01$   $\mu$ M and  $39.73 \pm 7.82$   $\mu$ M, respectively (Table 1).

**Table 1.** Molecular docking of 28 chamomile compounds bound to NF- $\kappa$ B p65-RelA homodimer (PDB ID: 1NFI). The lowest binding energies (LBE, kcal/mol) predicted inhibition constants ( $\mu$ M), and the pharmacophores with the amino acid residues involved in binding of the compounds are represented.

| Compounds              | LBE (kcal/mol)    | pKi ( $\mu$ M)   | Pharmacophores   |
|------------------------|-------------------|------------------|--|
| $\beta$ -Amyryn        | $-8.70 \pm <0.01$ | $0.42 \pm <0.01$ | GLU222, <b>ASP223</b> , <b>ILE224</b> , GLU225, <b>PHE239</b> , PRO275                                       |

The top 6 of the 212 compounds were selected for further detailed studies. They were bound to three different pockets within two domains (Figure 1B). In the dimerization domain, daucosterol and apigenin shared the same pocket. On the other hand,  $\beta$ -amyrin,  $\beta$ -sitosterol,  $\beta$ -eudesmol, and triptolide were also bound to the same site, while myricetin was bound to the head of the N-terminal domain. Their interaction and binding with the protein were displayed as two- and three-dimensional figures (Figure 1C–H). Triptolide, as an established inhibitor of NF- $\kappa$ B, was used as a positive control [50]. Its interaction with NF- $\kappa$ B p65 RelA is visualized in Figure 1I.

**Figure 1.** In silico binding of selected phytochemicals extracted from chamomile (*Matricaria chamomilla*) and triptolide (positive control) to NF- $\kappa$ B. Molecular docking analyses have been performed with NF- $\kappa$ B -RelA (PDB ID: 1NFI). (A) The lowest binding energies (LBE, kcal/mol) of the top 28/212 compounds (=10.4%) significantly correlated with the predicted inhibition constants (pKi,  $\mu$ M) ( $p = 2.61 \times 10^{-6}$ ;  $r = 0.76$ ). (B) The top 6/212 compounds were bound to different pockets within two domains. The interactions of these six compounds with the amino acids of NF- $\kappa$ B are displayed as 2D and 3D figures: (C)  $\beta$ -amyrin, (D)  $\beta$ -sitosterol, (E) myricetin, (F) daucosterol, (G)  $\beta$ -eudesmol, (H) apigenin, and (I) triptolide (positive control).

### 3.2. Microscale Thermophoresis

To exemplarily verify the molecular docking results, we performed microscale thermophoresis (MST) with  $\beta$ -amyrin and NF- $\kappa$ B. Decreasing concentrations of  $\beta$ -amyrin were titrated against the human recombinant NF- $\kappa$ B. The working solutions of  $\beta$ -amyrin were obtained by diluting the stock solution in DMSO with working buffer (MST buffer). The equilibrium constants  $K_D$  confirmed that  $\beta$ -amyrin was indeed bound to NF- $\kappa$ B. By using the law of mass action, a  $K_D$  value of  $943 \pm 113$  nM was determined (Figure 2A).

**Figure 2.** In vitro binding to and inhibition of NF- $\kappa$ B for selected phytochemicals extracted from chamomile (*Matricaria chamomilla*) and triptolide (positive control). (A) Binding of  $\beta$ -amyryn to NF- $\kappa$ B as determined through microscale thermophoresis (MST). The resulting binding kinetics is shown as normalized fluorescence (LED power: 40%; MST power: 10%). (B) Inhibition of NF- $\kappa$ B activity using an NF- $\kappa$ B reporter assay. The percentages of the NF- $\kappa$ B rest activity are shown after 24 h treatment with  $\beta$ -amyryn,  $\beta$ -sitosterol,  $\beta$ -eudesmol, daucosterol, myricetin, and apigenin at concentrations of 0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M followed by 100 ng/mL of TNF- $\alpha$  for 24 h (\*  $p < 0.05$ ). (C,D) Pearson correlation of NF- $\kappa$ B rest activity (%) vs. lowest binding energy (kcal/mol) of the six selected compounds at concentrations of (C) 0.1  $\mu$ M and (D) 1  $\mu$ M. The correlation using a concentration of 10  $\mu$ M was statistically not significant. The mean values  $\pm$  SD of three independent experiments are shown. (\*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ ).

### 3.3. NF- $\kappa$ B Reporter Assay

To verify the results predicted in silico, these six phytochemicals were subjected to an NF- $\kappa$ B reporter cell assay. We measured the remaining NF- $\kappa$ B activity upon treatment with these compounds at concentrations of 0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M (Figure 2B).  $\beta$ -Amyryn was the most effective inhibitor of NF- $\kappa$ B activity, with remaining activity values of 38.9%  $\pm$  7.3, 52.2%  $\pm$  6.2, and 60.3%  $\pm$  8.7, respectively. Daucosterol had the lowest inhibitory activity with activity percentages of 6.1%  $\pm$  7 (0.1  $\mu$ M), 16.2%  $\pm$  2.9 (1  $\mu$ M), and 20.8%  $\pm$  2.7 (10  $\mu$ M). Triptolide as a positive control strongly inhibited the NF- $\kappa$ B activity.

To see whether the rest activity measured in vitro may correlate with the LBE values determined in silico, we performed correlation analyses. The NF- $\kappa$ B rest activity (%) significantly correlated with the LBE values (kcal/mol) at 0.1  $\mu$ M ( $p = 0.02$ ;  $r = 0.89$ ) and 1  $\mu$ M ( $p = 0.03$ ;  $r = 0.85$ ). The treatment at 10  $\mu$ M did not correlate with the LBE values  $r = -0.15$  (Figure 2B–D).

### 3.4. Assessment of Oxidative Stress

It is well-known that high levels of reactive oxygen species (ROS) activate NF- $\kappa$ B and foster the inflammation process. In addition, NF- $\kappa$ B increases ROS generation during inflammation [51,52]. Therefore, we measured the ROS levels as a parameter of oxidative

stress. Untreated HEK-Blue Null 1 (HBN1) cells exhibited very low ROS levels (0.68%). However, if the cells were exposed to hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) as the positive control, the ROS generation significantly increased by 11.63% ( $p = 0.02$ , compared with untreated cells as the negative control). The combination of  $\text{H}_2\text{O}_2$  and tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) as a proinflammatory cytokine further increased the ROS generation up to 14.13% ( $p = 0.005$ , compared with the negative control). In contrast,  $\beta$ -amyrin treatment significantly decreased the  $\text{H}_2\text{O}_2$ - and TNF- $\alpha$ -induced ROS generation by 12.30% ( $p = 0.1$ ), 10.83% ( $p = 0.05$ ), and 8.80% ( $p = 0.01$ ) at 0.1  $\mu\text{M}$ , 1  $\mu\text{M}$ , and 10  $\mu\text{M}$ , respectively (Figure 3).

**Figure 3.** Effect of  $\beta$ -amyrin on the generation of reactive oxygen species (ROS) in HEK-Blue Null 1 (HBN1). The cells were treated with 100  $\mu\text{M}$  of  $\text{H}_2\text{O}_2$  (15 min) and 100 ng/mL of TNF- $\alpha$  (3 h) with and without  $\beta$ -amyrin at concentrations of 0.1  $\mu\text{M}$ , 1  $\mu\text{M}$ , and 10  $\mu\text{M}$  (24 h). The statistical analysis was performed by using the paired student's *t*-test. \*  $p = 0.05$  (1  $\mu\text{M}$ ) and \*\*  $p = 0.01$  (10  $\mu\text{M}$ ) compared with TNF- $\alpha$ - and  $\text{H}_2\text{O}_2$ -treated control cells, #  $p = 0.02$  (cells treated with  $\text{H}_2\text{O}_2$ ), and ##  $p = 0.005$  (cells treated with TNF- $\alpha$  and  $\text{H}_2\text{O}_2$ ) compared with untreated cells.  $\beta$ -amyrin significantly reduced ROS generation. DMSO treatment served as the solvent control. The mean values  $\pm$  SD of three independent experiments are shown.

### 3.5. Measurement of the Mitochondrial Membrane Potential

Mitochondria are not only essential for ATP generation and programmed cell death but also play a key role in inflammation [53]. We investigated whether the inhibition of NF- $\kappa\text{B}$  after TNF- $\alpha$  induction affected the mitochondrial membrane potential and whether  $\beta$ -amyrin reversed this effect. HEK-Blue Null1 cells were treated with 10  $\mu\text{M}$  of  $\beta$ -amyrin for 24 h and with TNF- $\alpha$  for 3 h. As a positive control, cells were treated with 10  $\mu\text{M}$  of vinblastine (Figure 4). Using flow cytometry and JC-1, we measured a considerable breakdown of the mitochondrial membrane potential (MMP) upon treatment with  $\beta$ -amyrin or vinblastine compared to the untreated control (Figure 4A).  $\beta$ -Amyrin led to a 52.6% increase in the population of cells with disrupted mitochondrial membrane potential (indicative of apoptotic or dead cells), while only 47.6% of cells maintained their MMP (and their viability). In comparison, vinblastine had an effect of 73.6% living cells and 26.6% dead cells (Figure 4B).

**Figure 4.** Flow cytometric determination of mitochondrial membrane potential (MMP) in HEK-Blue Null 1 Cells through JC-1 staining. Cells were left untreated (control) or treated with 10  $\mu\text{M}$  of  $\beta$ -amyryn or vinblastine for 24 h, followed by 100 ng/mL of TNF- $\alpha$  for 3 h. (A) Representative histograms; (B) statistical analysis cells with disrupted MMP (dead cells) or intact MMP (healthy cells). Mean values  $\pm$  SD of three independent experiments are shown. The results are significant at \*\*  $p < 0.01$  for death cells and \*  $p < 0.05$  for living cells if compared to the control DMSO untreated cells (paired two-tailed  $t$ -test).

### 3.6. Cytotoxicity and Oncobiogram Analyses

The link between inflammation and carcinogenesis is well-established [54]. Accordingly, the first part of the analysis was to compare the effect of the multiple chamomile compounds on the cell viability of 60 cell lines originating from different tumor types. While (+)-catechin,  $\beta$ -sitosterol, daucosterol, caffeic acid, and  $\beta$ -eudesmol were inactive or only minimally active, the strongest inhibition was observed with apigenin and farnesol. Lupeol and quercetin showed intermediate cytotoxicity (Figure 5A–C). Because apigenin and farnesol as the most cytotoxic compounds in this panel were already the subjects of previous investigations by us [19,20,55–57], we chose quercetin and lupeol for further analyses.

As  $\beta$ -amyryn was not included in the NCI database, we performed a growth inhibition assay, which revealed that  $\beta$ -amyryn did not exert any cytotoxic effect on the sensible leukemia cells. The highest inhibition was observed at a concentration of 100  $\mu\text{M}$  ( $26.2\% \pm 9.6$ ) (Supplementary Figure S1).

Then, we compiled the sensitivity of the NCI tumor cell lines towards lupeol and quercetin according to their origin, i.e., leukemia, melanoma, and brain tumors as well as carcinoma of the colon, ovary, breast, kidney, lung, and prostate. The mean  $\log_{10}\text{IC}_{50}$  (M) values for quercetin and lupeol were compared with those for chlorambucil as an established anticancer drug (control). It is evident from the data shown in Figure 5D that all three compounds exhibited the greatest growth-inhibitory efficacy in leukemia cells compared to the cell lines of other tumor types. Melanoma cells were most resistant to quercetin. With some variations, the cytotoxicity of both lupeol and quercetin was approximately comparable to that of chlorambucil.

While natural products are bioactive through multiple mechanisms [58,59], the exact modes of action of lupeol and quercetin are unknown. Therefore, we correlated the  $\log_{10}\text{IC}_{50}$  values of lupeol and quercetin with those of 91 standard agents with known modes of action (Figure 5E). Both lupeol and quercetin were most frequently correlated with microtubule inhibitors and mTOR inhibitors. Therefore, we subjected both compounds to oncobiogram analysis by compiling the correlation coefficients ( $r$ -values) of lupeol and quercetin to those of 10 known microtubule inhibitors (Figure 5F). The analysis favored the hypothesis that lupeol and quercetin might also act as tubulin inhibitors.

**Figure 5.** Cytotoxicity and oncobiogram analyses. Chemical structures of (A) lupeol and (B) quercetin. (C) Cytotoxicity of six selected phytochemicals from chamomile to the NCI tumor cell line panel plotted as a mean log<sub>10</sub>IC<sub>50</sub> for each tumor type. (D) The cytotoxicity of lupeol and quercetin in cell lines of different tumor types compared with the established anticancer drug chlorambucil as the positive control. (E) Cross-resistance profiling of lupeol and quercetin to 91 standard drugs with known modes of action against tumor cells. (F) Oncobiogram for lupeol and quercetin. The correlation coefficients for lupeol and quercetin for 10 known tubulin inhibitors are plotted.

### 3.7. Inhibition of $\alpha$ -Tubulin by Lupeol and Quercetin as Detected through Confocal Immunofluorescence Microscopy

The oncobiogram analysis showed that both lupeol and quercetin might act as microtubule inhibitors. To validate this hypothesis, we treated the U2OS cells transfected with GFP- $\alpha$ -tubulin with lupeol and quercetin (0.1  $\mu$ M, 1  $\mu$ M, and 10  $\mu$ M). Vincristine (1  $\mu$ M) was used as the control drug to monitor the inhibition of microtubule polymerization, and paclitaxel (1  $\mu$ M) was used as the control drug to monitor the inhibition of microtubule depolymerization. As can be seen in Figure 6, both lupeol and quercetin affected  $\alpha$ -tubulin in a comparable manner to vincristine, indicating that they may have inhibited microtubule polymerization rather than depolymerization.

### 3.8. Binding of Lupeol and Quercetin to $\alpha$ -Tubulin as Detected through Molecular Docking

To further investigate the possible interactions of lupeol and quercetin to  $\alpha$ -tubulin, we performed molecular docking. For quality control of the results obtained in this series of molecular dockings, we first correlated the LBE and pKi values. The Pearson correlation test showed that all LBE values (kcal/mol) correlated significantly with their respective pKi ( $\mu$ M) values at  $p = 0.004$  and  $r = 0.85$  (Figure 7A).

The in silico analysis demonstrated that lupeol and quercetin had higher binding affinities to  $\alpha$ -tubulin at the vincristine binding site compared to the binding sites of paclitaxel and colchicine (Figure 7A). Specifically, the calculation of low binding energy (LBE) for lupeol interacting with  $\alpha$ -tubulin at the vincristine's binding site was lower than its LBE value at paclitaxel's binding site, with values of  $-8.62 \pm 0.04$  kcal/mol and  $-7.12 \pm 0.01$  kcal/mol, respectively. Similarly, quercetin had an LBE with the protein at vincristine's binding site compared to paclitaxel's binding site, with values of  $-6.77 \pm 0.06$  kcal/mol and  $-5.99 \pm 0.29$  kcal/mol, respectively. In contrast, both compounds had less affinity with the  $\alpha$ -tubulin if docked at the colchicine's binding site, with calculated LBE values of  $-4.48 \pm 0.08$  kcal/mol for lupeol and  $-4.72 \pm 0.15$  kcal/mol for quercetin (Table 2). Figure 7C–E show the 3D and 2D docking poses of vincristine, quercetin, and lupeol, highlighting the amino acid residues involved in the binding of each molecule to  $\alpha$ -tubulin at the vincristine binding site.

**Figure 6.** Confocal immunofluorescence microscopy of the microtubule network in U2OS cells upon treatment with (A) quercetin and (B) lupeol at concentrations of 0.1  $\mu\text{M}$ , 1  $\mu\text{M}$ , and 10  $\mu\text{M}$  for 24 h. Vincristine (1  $\mu\text{M}$ ) and paclitaxel (1  $\mu\text{M}$ ) served as positive controls and DMSO as the negative control. The cells were imaged using a Thunder Imager Live Cell microscope with a 63 $\times$ /1.40 NA objective lens (HC PL APO CS2 63 $\times$ /1.40 OIL UV). The microtubules were visualized using green fluorescence for GFP (green), and the images were merged with DAPI (blue) to highlight the nucleus.

**Figure 7.** Molecular docking analysis of lupeol and quercetin to tubulin (5N5N). (A) Illustrates the binding sites of vincristine, paclitaxel, and colchicine to  $\alpha$ - and  $\beta$ -tubulin. On the right, a zoomed-in view shows lupeol and quercetin binding to the same pocket as vincristine. (B) The correlation of the predicted inhibition constants (pKi, mM) vs. the lowest binding energies (LBE, kcal/mol) ( $p = 0.004$ ,  $r = 0.85$ ). (C,D) Presents 3D and 2D illustrations of the interaction of lupeol, quercetin, and vincristine with the amino acids of  $\alpha$ -tubulin docked at vincristine’s binding site. (C) Vincristine, (D) quercetin, and (E) lupeol.

**Table 2.** Molecular docking of lupeol and quercetin bound to  $\alpha$ - and  $\beta$ -tubulin (PDB ID: 5N5N). The lowest binding energies (LBE, kcal/mol), the predicted inhibition constants ( $\mu\text{M}$ ), and the pharmacophores are represented.

### 3.9. Cell Cycle Analysis

Both quercetin and lupeol significantly induced G2/M phase arrest in U2OS cells at  $4 \times \text{IC}_{50}$  after 72 h compared to the negative control (DMSO) (Figure 8). Quercetin induced cell cycle arrest with 86.6% of the cells in the G2/M phase ( $p = 0.0001$ ) and 4.9% in the S phase ( $p = 0.4$ ). Interestingly, a small but significant portion of cells (7.9%) was also increased in the G0/G1 phase ( $p = 0.0001$ ), indicating that arresting the cells in the G2/M phase was not the only consequence of treatment. As expected, the positive control vincristine ( $1 \times \text{IC}_{50}$ ) induced cell cycle arrest, with 83.6% of cells in the G2/M phase ( $p = 0.001$ ), 5.9% in the S phase ( $p = 0.2$ ), and 9.3% in the G0/G1 phase ( $p = 0.001$ ).

Similarly, lupeol also induced cell cycle arrest in U2OS cells, with 90.9% of the cells in the G2/M phase ( $p = 0.0002$ ), 5.3% in the S phase ( $p = 0.05$ ), and 3.8% in the G0/G1 phase ( $p = 0.0001$ ). Vincristine was used in parallel as the positive control in this experiment, too. A concentration of  $1 \times \text{IC}_{50}$  induced cell cycle arrest, with 82.3% of cells in the G2/M phase ( $p = 0.002$ ), 6.0% in the S phase ( $p = 0.02$ ), and 12.3% in the G0/G1 phase ( $p = 0.001$ ).

### 3.10. Drug Resistance Profiling of Lupeol and Quercetin

The question arises as to whether lupeol and quercetin are recognized by classical drug resistance mechanisms and, therefore, whether their activity is hampered by these drug resistance mechanisms. Utilizing the NCI database [40], we correlated the  $\log_{10}\text{IC}_{50}$  values of lupeol and quercetin with various mechanisms of multidrug resistance in the NCI panel of tumor cell lines (Table 3). Notably, we did not observe an involvement of the two compounds in any drug resistance phenotype, except for one correlation between quercetin and *ABCB5* mRNA expression analyzed through qPCR. This correlation was not significant if mRNA expression was analyzed through microarray hybridization. These findings indicate that these two compounds from chamomile might be useful in inhibiting tumor cells that are otherwise resistant to drugs.

**Figure 8.** Cell cycle arrest of U2OS cells by quercetin and lupeol. (A) Debris was gated out (SSC-A vs. FSC-A) with the first gate. (B) With the second gate (FSC-H vs. FSC-A), only single cells of normal morphology were gated. Duplets were gated out. (C,D) Three-dimensional representation of DNA histograms of U2OS cells exposed to 1 × IC<sub>50</sub> and 4 × IC<sub>50</sub> quercetin and lupeol for 72 h. DMSO was used as the negative control, and 1 × IC<sub>50</sub> vincristine was used as the positive control. (C) Cells treated with lupeol and (D) cells treated with quercetin. The histograms were obtained through flow cytometry using an excitation of 488 nm and an emission wavelength of 530 nm. (E,F) Bar diagrams showing the distinct phases of cell cycle upon treatment with quercetin and lupeol for 72 h. (E) Cells treated with lupeol and (F) cells treated with quercetin. The bar diagrams were created through the calculation of the mean values ± SD of three independent experiments. \*\*\* *p* < 0.001, \*\* *p* < 0.01, and \* *p* < 0.05 compared to the negative control using paired two-tailed *t*-test.

**Table 3.** Correlation between the log<sub>10</sub>IC<sub>50</sub> values for quercetin and lupeol and classical drug resistance mechanisms in the NCI tumor cell line panel.

### 3.11. Cytotoxicity Assays for Lupeol and Quercetin

Because the analysis of the NCI cell line panel indicated the activity of both lupeol and quercetin against classical drug resistance mechanisms, we performed resazurin assays to investigate whether these results obtained through correlation analyses could be verified by independent in vitro experimentation.

The dose–response curves in Figure 9 show that multidrug-resistant P-glycoprotein-overexpressing CEM/ADR5000 leukemia cells were cross-resistant to quercetin (degree of resistance: >7.3-fold) and lupeol (degree of resistance: 3.2-fold). The glioblastoma transfected cells with  $\Delta$ EGFR (U87.MG/ $\Delta$ EGFR) were 2.3-fold resistant to quercetin and 7.4-fold resistant to lupeol compared to wild-type U87.MG cells. Colorectal TP53 knockout cells (HCT116 p53<sup>-/-</sup>) were only weakly resistant to quercetin and lupeol (1.4-fold and 1.8-fold, respectively) compared to their corresponding wild-type cells (HCT116 p53<sup>+/+</sup>). All degrees of resistance were, thus, rather low, indicating no or only very low levels of resistance to lupeol and quercetin. These results fit the data obtained from the NCI tumor cell line panel, showing no correlations between the log<sub>10</sub>IC<sub>50</sub> values and the classical resistance mechanisms. The IC<sub>50</sub> values of U2OS for quercetin and lupeol were higher than those found for most other cell lines tested, indicating that these osteosarcoma cells were more resistant to these two compounds.

**Figure 9.** Dose–response curves of quercetin and lupeol as determined through resazurin assay. The mean values and standard deviation values are from three independent experiments. The tumor cells were subjected to treatment with each compound at concentrations of 10 μM, 25 μM, 50 μM, and 100 μM for 72 h. (A) Sensitive CCRF-CEM and the drug-resistant P-glycoprotein overexpressing CEM/ADR5000 leukemia cells. (B) U87/ΔEGFR transfected with a deletion-activated cDNA of EGFR and its wild-type U87.MG glioblastoma cells. (C) HCT116 p53<sup>+/+</sup> and knockout HCT116 p53<sup>-/-</sup> colorectal cancer cells. (D) U2OS osteosarcoma cells.

### 3.12. Cell Death Detection

We investigated the mode of cell death in CCRF-CEM cells upon treatment with lupeol and quercetin for 72 h. The FITC-conjugated annexin V/PI assay was used to distinguish between living, early apoptotic, late apoptotic, and necrotic cells. Annexin V staining is usually detected in early and late apoptosis, while PI staining indicates late apoptosis and necrosis. Figures 10 and 11 show that both compounds significantly induced necrosis compared to the negative control. Quercetin induced necrosis in 56.40% of CCRF-CEM cells ( $p = 0.001$ ), while lupeol induced necrosis in 74.33% of cells ( $p = 0.006$ ). In contrast, early or late apoptosis was detected at low or negligible percentages.

Similarly, the FITC-conjugated annexin V/PI assay was conducted in U2OS cells after treatment with quercetin and lupeol for 72 h. As shown in Figure 11, the cells were rather resistant towards the two compounds, which did not significantly impact the onset of apoptosis but rather necrosis.

**Figure 10.** Detection of cell death in CCRF-CEM cells using flow cytometry and annexin-V/PI staining using a flow cytometer. (A,B) Cells treated for 72 h with  $0.25 \times \text{IC}_{50}$ ,  $0.5 \times \text{IC}_{50}$ ,  $1 \times \text{IC}_{50}$ ,  $2 \times \text{IC}_{50}$ , and  $4 \times \text{IC}_{50}$  of quercetin and lupeol, respectively. DMSO was used as the negative control. (A) Cells treated with quercetin and (B) cells treated with lupeol. Q1 represents necrotic cells (–) annexin V/(+) PI; Q2 represents late apoptotic cells exhibiting annexin V (+)/PI (+); Q3 represents early apoptotic cells (+) annexin V/(–) PI; Q4 represents viable cells (–) annexin V/(–) PI. (C,D) Bar diagrams representing the percentages of cells in the different quadrants. (C) Effects of quercetin and (D) effects of lupeol. The treatment of both compounds at increasing concentrations significantly enhanced the percentage of necrotic cells. \*\*\*  $p < 0.001$ , \*\*  $p < 0.01$ , and \*  $p < 0.05$  compared to the negative control using paired two-tailed  $t$ -test. The bar diagrams were created through the calculation of the mean values  $\pm$  SD of three independent experiments.

**Figure 11.** Detection of cell death in U2OS cells using flow cytometry and annexin-V/PI staining using a flow cytometer. (A,B) Cells treated for 72 h with  $0.5 \times IC_{50}$ ,  $1 \times IC_{50}$ ,  $2 \times IC_{50}$ , and  $4 \times IC_{50}$  of lupeol and quercetin, respectively. (C,D) represent bar diagrams of the percentage of cells in quadrum treated with lupeol (C) and quercetin (D). For details, see Figure 10. Treatment with both compounds at  $4 \times IC_{50}$  showed a tendency for increased necrosis, which was, however, not statistically significant compared to the negative control.

### 3.13. Western Blotting

The NF- $\kappa$ B reporter assay in Figure 2 indicated that the selected chamomile compounds inhibited the activity of the NF- $\kappa$ B promoter in the context of anti-inflammatory NF- $\kappa$ B activity. As NF- $\kappa$ B inhibition also plays a role in the apoptosis of cancer cells, we performed a Western blotting experiment to examine the effect of three chamomile compounds ( $\beta$ -amyryn, lupeol, and quercetin) on the protein expression level of NF- $\kappa$ B 65.  $\beta$ -Amyryn and quercetin ( $50 \mu\text{M}$ ) increased cytoplasmic NF- $\kappa$ B expression, while lupeol displayed non-significant tendencies (Figure 12A).

### 3.14. Quantitative Real-Time RT-PCR

*IL-1 $\beta$*  and *IL-6* are known downstream cytokines regulated by NF- $\kappa$ B that are important for mediating proinflammatory and cell-proliferative signals. All three compounds significantly downregulated the expression of the genes encoding *IL-1 $\beta$*  and *IL-6*, particularly at  $50 \mu\text{M}$  (Figure 12C). Notably, quercetin was significantly more effective in downregulating the two genes compared to the other two compounds, with a fold-change in  $\log_2$  of  $-1.11$  for *IL-6* ( $p = 0.01$ ) and  $-0.71$  for *IL-1 $\beta$*  ( $p = 0.01$ ). Conversely,  $\beta$ -amyryn displayed the lowest downregulatory activity for *IL-6*, with fold-changes of  $\log_2 -0.29$  for *IL-6* and  $-0.56$  for *IL-1 $\beta$*  ( $p = 0.01$ ). Furthermore, lupeol decreased the genes with  $\log_2$  values of  $-0.54$  for *IL-6* ( $p = 0.01$ ) and  $-0.65$  for *IL-1 $\beta$*  ( $p = 0.02$ ).

**Figure 12.** Expression of NF-κB and downstream genes. **(A)** Western blotting analysis of NF-κB in HEK-Blue Null1 cells treated with 10 μM or 50 μM of β-amyryn, quercetin, and lupeol for 24 h, followed by 24 h of TNF-α at 100 ng/mol. **(B)** The percentages of NF-κB expression in the cell. **(C)** qRT-PCR analysis of *IL-1β* and *IL-6* gene expression in HEK-Blue Null 1 cells treated with 10 μM or 50 μM of β-amyryn, quercetin, and lupeol for 24 h with TNF-α 100 ng/mL for another 24 h. The statistical analysis was performed through the paired one-tailed *t*-test (\*\*  $p \leq 0.01$ ) (\*  $p \leq 0.05$ ) from three independent trials.

### 3.15. Proteome Analysis

If all or most of the classical drug resistance mechanisms are not operative for lupeol and quercetin, the question arises as to which factors do determine sensitivity and resistance to these two drugs. Therefore, we conducted a COMPARE analysis by correlating the expression levels of 3171 proteins in the 60 tumor cell lines from the NCI database [40] with the  $\log_{10}IC_{50}$  values of both lupeol and quercetin. Subsequently, the top 40 proteins were assembled, and 20 were directly correlated with the two compounds and 20 were reversely correlated. Finally, we generated a two-dimensional clustering and color-coded heat map using a hierarchical Ward cluster method, where, in one dimension, the expression profiles of the 40 proteins appear and, in a second dimension, the different cell lines appear (Figures 13 and 14). The  $\log_{10}IC_{50}$  values for lupeol and quercetin, which were not included in the cluster calculations, are shown on the right side of the heat maps for illustration. The cellular responsiveness to both lupeol and quercetin was determined by comparing individual  $\log_{10}IC_{50}$  values to the median value across all cell lines. If the  $\log_{10}IC_{50}$  value was lower than the median, the cell lines were categorized as sensitive; if it was above the median, the cells were defined as resistant.

**Figure 13.** Cluster analysis in a 2D colored heat map of proteins' expression in NCI tumor cell lines responding to lupeol. Clusters A and B represent the top 40 proteins, and clusters 1–3 show the tumor cell lines. The cell lines were clustered according to their degrees of relatedness to each other based on their protein expression included in the analysis. Color code: red, 0–25% quartile; orange, 26–50% quartile; grey, median value; light green, 50–75% quartile; and dark green, 76–100% quartile. Depending on individual  $\log_{10}IC_{50}$  values, the responsiveness of the cell lines to lupeol was classified as sensitive if their  $\log_{10}IC_{50}$  values were lower than the median value of all cell lines (marked in yellow) and as resistant if their  $\log_{10}IC_{50}$  values were higher than the median value (marked in red). The  $\chi^2$  test shows a statistical significance ( $p = 1.44 \times 10^{-4}$ ) upon comparing the two clusters of protein expression in the cell lines, where clusters 1 and 2 contained mainly resistant cell lines to both lupeol and quercetin, respectively, and cluster 3 contained mainly sensitive cell lines.

For both lupeol and quercetin, we obtained three clusters (clusters 1–3) showing the individual protein expression. Furthermore, we obtained two clusters of cell lines (clusters A and B) (Figures 13 and 14). These clusters were then correlated with the  $\log_{10}IC_{50}$  values (which were not included in the cluster calculation). Interestingly, clusters 1 and 2 predominantly included lupeol/quercetin-resistant cell lines, while cluster 3 predominantly contained sensitive cell lines. Cluster A predominantly contained cell lines with high protein expression in cluster 1 and low expression in cluster 3, while in cluster B, the protein expression was the opposite (low in cluster 1 and high in cluster 3). Afterwards, we calculated the difference between sensitive and resistant cell lines using the  $\chi^2$  test. The results showed that the distribution of the three clusters was statistically significant for both lupeol ( $p = 1.44 \times 10^{-4}$ ) and quercetin ( $p = 0.044$ ) (Figures 13 and 14).

**Figure 14.** Cluster analysis in a 2D colored heat map of proteins' expression in NCI tumor cell lines responding to quercetin. The  $\chi^2$  test shows a statistical significance ( $p = 0.044$ ). For further details, see Figure 13.

Each of the 40 proteins was identified through this approach to determine the sensitivity or resistance to lupeol or quercetin. These proteins have been compiled along with their protein symbols, full names, cellular functions, and functional categories in Supplementary Tables S1 and S2. Although these proteins seemed to be unrelated at first sight, it was interesting to observe that they belonged to some common functional categories. These categories are shown in Table 4.

**Table 4.** Functional categories of proteins identified through the proteomic analyses for lupeol and quercetin, as shown in Figures 13 and 14.

| Functional Categories                  | Protein Symbols (Lupeol Analysis)                  | Protein Symbols (Quercetin Analysis)                            |
|--|--|---|

### 3.16. Kaplan–Meier Survival Analysis

Because NF- $\kappa$ B is known for its anti-proliferative, anti-apoptotic, and anti-inflammatory activities in the cell [60], we wanted to survey the role of NF- $\kappa$ B expression for the survival prognosis of cancer patients. We performed Kaplan–Meier survival analysis with the help of the KM-Plotter database. Out of 21 cancer types, the analysis revealed that the higher the *NFKB2* mRNA expressed, the lower the survival time for patients with renal clear cell carcinoma compared with patients with low *NFKB2* expression. Moreover, patients with high *NFKB2* expression in grade 3 renal carcinoma died significantly earlier than those with a low expression. Interestingly, the female patients with renal carcinoma had significantly longer survival times compared with males if *NFKB2* mRNA expression was low. Similarly, patients with low neoantigen load and low *NFKB2* mRNA expression in their renal carcinoma cell type had a better survival prognosis than those with high *NFKB2* expression and a significantly higher survival time than the patients with a low mutational rate (Figure 15). These data indicated that the inhibition of NF- $\kappa$ B could indeed be beneficial in the prevention and treatment of renal carcinoma.

**Figure 15.** Kaplan–Meier analysis from the KM-Plotter database of overall survival time (months) for renal clear cell carcinoma cells correlating with the expression of *NFKB2* mRNA. (A–F) Different patient profiles where NF- $\kappa$ B expression correlated significantly with the overall survival time.

## 4. Discussion

Chamomile tea is not only used for its exquisite taste but also its numerous health-promoting effects. Renowned for centuries, chamomile contains metabolites that possess anti-inflammatory, antioxidant, and relaxant properties [61,62]. Over decades, many studies have revealed the anti-inflammatory effect of chamomile both in vitro and in vivo [63]. They have demonstrated the inhibitory effect of chamomile extract against markers and pathways at the molecular and cellular levels [64,65]. These findings were complemented by in vivo research, where chamomile compounds exhibited anti-inflammatory effects if tested in animals [66,67]. Adding to this, various clinical studies have shown evidence

of the anti-inflammatory effect of chamomile if tested in patients with different types of inflammatory disease [65,68,69]. Moreover, chamomile has garnered attention for its potential in cancer prevention and treatment [70–72]. In vitro results have suggested that chamomile extracts may possess anticancer properties, showing inhibitory effects on the proliferation of cancer cells and in some cases on programmed cell death [12,13,73–77]. While there is limited evidence in vivo, some preliminary evidence supports the potential of chamomile as an anticancer and preventive agent [78–80]. The entangled connection between inflammation and carcinogenesis may make a reasonable contribution to this point of view [81,82].

In the same entangled manner, the transcription factor NF- $\kappa$ B was proven to play a role in both inflammation and carcinogenesis [83]. NF- $\kappa$ B not only controls the inflammatory responses with its transcriptional activity on several proinflammatory promoters [84] but also has a crucial role in regulating apoptosis and cell proliferation, mostly by favoring cell survival mechanisms and, therefore, contributing to the initiation and progression of tumors [85,86]. Additionally, NF- $\kappa$ B pathways also play a pivotal role in the development of resistance against anticancer drugs [87,88]. Interestingly, the development of tumors is often driven by similar mechanisms that also cause drug resistance. It is in the nature of the biological system of all organisms to detoxify and excrete harmful substances, such as toxic metabolic products used in chemotherapy, through the activation of pro-survival pathways. This will then annul the induction of cell death and enhance the continuous progression of the tumor in the body [89–91].

These findings and observations prompted the question of whether chamomile or its derivatives inhibit NF- $\kappa$ B. NF- $\kappa$ B activation or inhibition plays a key role in cellular processes, such as cell survival, cell growth, cell proliferation, and even cell death in stem cells and different cancer cells, including leukemia [92–95]. To address this, we initiated virtual drug screening to investigate the bindings between 212 chamomile compounds to NF- $\kappa$ B. Subsequently, 28 compounds were further selected for a computational assay in which we calculated the LBE and pKi values. Among these 28 molecules, 15 exhibited LBE values consistently below  $-6$  kcal/mol. Correspondingly, the pKi values demonstrated a diverse range, fluctuating between  $0.42 \pm <0.01$   $\mu$ M for  $\beta$ -amyryn and  $46.78 \pm 0.12$   $\mu$ M for apigenin. Six compounds were selected from these results for further in vitro experiments.  $\beta$ -Amyryn,  $\beta$ -sitosterol,  $\beta$ -eudesmol, daucosterol, and myricetin were chosen depending on their binding energy, including a range from the highest to the average and lowest values. Apigenin, with higher binding, was chosen for its popularity and proper comparison with the other compounds. Using an inhibitory NF- $\kappa$ B reporter cell assay where the rest activity of NF- $\kappa$ B was measured,  $\beta$ -amyryn exhibited the highest percentage of inhibition. In contrast, daucosterol demonstrated the lowest inhibitory activity. These experimental results confirm our in silico predictions. Hence, the regression analysis of the data showed that NF- $\kappa$ B rest activity (%) significantly correlated with the LBE values. Additionally, we validated the authenticity of our data using microscale thermophoresis (MST). This result further confirmed the binding of  $\beta$ -amyryn to NF- $\kappa$ B.

It is now evident that activated NF- $\kappa$ B enhances the expression of proinflammatory genes in a positive feedback loop, leading to increased ROS generation in the cell. Elevated ROS levels during chronic inflammatory diseases or cancer can in return further activate NF- $\kappa$ B and upregulate immune responses [96,97]. Accordingly, to validate this relationship, we performed an ROS generation assay using HEK-Blue Null 1 cells treated with  $\beta$ -amyryn and exposed to 100 ng/mL of TNF- $\alpha$  and 10  $\mu$ M of H<sub>2</sub>O<sub>2</sub>, thus creating a high oxidative microenvironment within the cell. The results demonstrated that  $\beta$ -amyryn reduced ROS levels significantly. Moreover, it is well-established that both acute and chronic inflammatory diseases are characterized by dysfunction of mitochondria and aggregation of ROS generation. These factors can lead to cell damage or cell death. Alternatively, in other cases, they can trigger the activation of cell survival pathways and cell proliferation [98,99]. In this context, we examined whether the inhibition of NF- $\kappa$ B with  $\beta$ -amyryn might affect the mitochondrial membrane potential (MMP). Employing the MMP-JC1 assay on HEK-Blue

Null 1 treated with  $\beta$ -amyryn and TNF- $\alpha$  (to stimulate NF- $\kappa$ B activation), we observed a significant impact on the breakdown of MMP in the treated samples compared to the control.  $\beta$ -Amyryn treatment increased the population of MMP-disrupted cells by 52.6%. In comparison to vinblastine, 26.6% of the cell population were unhealthy or dead. These results highlight the promising potential of  $\beta$ -amyryn as a potential therapeutic agent for inflammatory diseases and oxidative-stress-related disorders, suggesting its applicability as a cancer-preventive agent or even an adjunctive treatment in cancer therapy.

This leads to the second part of this study, where we studied the therapeutic value of chamomile, particularly focusing on inflammation, cancer prevention, and overcoming drug resistance. We started with cytotoxicity and oncobiogram analyses comparing the effects of multiple chamomile compounds on the cell viability of 60 cell lines originating from various tumor types using the NCI60 database. Notably, quercetin and lupeol exerted significant cytotoxicity, with specific preferences against colon cancer for lupeol and melanoma for quercetin. The oncobiogram analysis further revealed correlations with microtubules and mTOR inhibitors, validating previous studies in which both quercetin and lupeol disturbed the polymerization of microtubules through their binding to tubulin [100,101] and inhibited the mTOR pathway [102,103]. The immunofluorescence microscopy experiment validated these findings, showing clear inhibition of the GFP- $\alpha$  tubulin polarization by lupeol and quercetin (at 10  $\mu$ M) comparable to the effect of vincristine (at 1  $\mu$ M). Given the key role of microtubules in cell stabilization and maintenance, the identification of novel tubulin inhibitors for tumor therapy remains essential [104]. Furthermore, the *in silico* assessment confirmed that both lupeol and quercetin have higher binding affinities with  $\alpha$ -tubulin if docked at vincristine's binding site compared to the two other known tubulin inhibitors, paclitaxel and colchicine.

It is well-established that paclitaxel enhances the stability of the microtubules, maintaining them in their polymerized form, which induces the activity of NF- $\kappa$ B through the same pathway as TNF- $\alpha$ . In contrast, colchicine and vincristine are known to destabilize and disturb the microtubule formation, which blocks the translocation of the cytoplasmic NF- $\kappa$ B p65 to the nucleus and reduces the activity of NF- $\kappa$ B through the TNF- $\alpha$  canonical pathway [105–107]. We hypothesize that lupeol and quercetin may act in the same manner as vincristine by inhibiting the microtubules and reducing the activity of NF- $\kappa$ B.

Microtubules are also important for immune reactions and inflammatory processes, as microtubule networks are involved in the migration of immune cells to inflamed tissues [108–110]. Thus, the inhibition of microtubules by anti-inflammatory compounds from chamomile might not only directly inhibit tumor cells but also suppress the activation and migration of inflammatory cells and thereby contribute to the decline of the inflammation process [111].

There is not only a connection between NF- $\kappa$ B and the microtubule but also cytokines. The NF- $\kappa$ B-mediated release of proinflammatory cytokines (e.g., *IL-1 $\beta$*  and *IL-6*) favors not only the activation of immune cells at inflamed sites in the body but also cell survival and cell proliferation. Because receptors for proinflammatory interleukins are expressed at both immune cells and tumor cells, their inhibition by natural products contributes to the suppression of tumor growth [112–114]. We found that  $\beta$ -amyryn, lupeol, and quercetin inhibited the expression of *IL-1 $\beta$*  and *IL-6*, a result that is consistent with the point of view that inhibition of interleukin production also causes the inhibition of tumor cell growth. At the same time, these three substances increased the expression of NF- $\kappa$ B of HEK-Blue Null1 cells. This can be explained by an inhibited translocation of NF- $\kappa$ B from the cytosol to the nucleus, which consequently leads to suppressed interleukin production due to the transcriptional activity of NF- $\kappa$ B in the nucleus. Because microtubules are involved in the translocation of NF- $\kappa$ B from the cytosol to the nucleus [115–117], microtubules inhibited by chamomile compounds may be unable to translocate cytosolic NF- $\kappa$ B to the nucleus, where it can bind to promoters of NF- $\kappa$ B downstream genes. Chamomile compounds may therefore act on multiple intracellular targets and pathways.

Recognizing that chemoresistance represents a major obstacle in cancer treatment, we conducted drug resistance profiling for quercetin and lupeol by correlating their values to classical drug resistance genes, including ABC transporters, oncogenes, tumor suppressors, and other mechanisms. The analysis indicated that the two compounds have no cross-resistance and are not involved in classical drug resistance mechanisms. This is a remarkable result as compounds combatting or bypassing resistance to clinically established drugs are urgently required.

We aimed to verify the correlation analyses with the NCI panel by using specific cell models that showed specifically overexpressed or knocked-out genes conferring drug resistance (P-glycoprotein, *EGFR*, *TP53*). While it is known that established cancer drugs can provoke high levels of resistance in tumors (e.g., CEM/ADR5000 cells were more than 1000-fold resistant to doxorubicin) [118], lupeol and quercetin showed no or only very low degrees of resistance of three or less. These results confirmed our bioinformatic analysis, indicating that both compounds are active against otherwise drug-resistant tumor cells and do not encounter major cross-resistance mechanisms.

It is reasonable to propose that chamomile holds not only the potential to prevent inflammation and cancer but also the ability to overcome drug resistance. This theorizes a dual role for chamomile as a preventive measure but also as an additive to cancer treatment, particularly in cells that exhibit resistance to conventional therapies. These insights open new possibilities for exploring chamomile compounds, such as  $\beta$ -amyryn, lupeol, and quercetin, as valuable assets in addressing the challenges posed by drug-resistant cancer cells. Further research and clinical studies could elucidate the full scope of chamomile's contributions to cancer prevention and treatment.

In this context, it was interesting that the cytotoxicity of both compounds in CCRF-CEM and U2OS cells was not caused by apoptosis as the most common mode of cell death but by necrosis. This might be a cell-type-specific effect as quercetin and lupeol have been reported to induce either apoptosis or necrosis (or necroptosis) in different cell lines [119–124]. Because apoptosis is driven by the balance of pro- and anti-apoptotic proteins in specific signaling cascades, it is known that mutations in specific genes encoding these proteins confer resistance to apoptosis [125–128]. As a consequence, cytotoxic insults may overcome apoptosis resistance by other cell death modes, such as necrosis [129].

Despite the fact that classical drug resistance mechanisms did not affect the responsiveness to lupeol and quercetin, it can be assumed that the different responsiveness of the NCI cell lines may be due to variations in the expression of genes that influence sensitivity and resistance to lupeol and quercetin. Therefore, the question arises as to what are the cellular factors that determine sensitivity or resistance to these two compounds. To explore this further, we analyzed the proteomic expression of the NCI tumor cell lines. In this analysis, we identified 40 proteins whose expression significantly correlated with sensitivity and resistance of the cell lines. Although the two sets of each of the 40 proteins identified through hierarchical cluster analysis for lupeol and quercetin seem to be heterogeneous at first sight, they belong to some common functional categories, i.e., protein and vesicle trafficking, DNA/RNA metabolism, immune function, cytoskeleton, mitochondrial function, cell proliferation and differentiation, cell death, channels and transporters, chaperone functions, signal transduction, and other functions (Table 4). Although these proteins have not been described or only scarcely described so far to determine sensitivity or resistance to lupeol or quercetin and the relationships found in our study are novel, most of the functional protein groups mentioned above are known to influence the response of tumor cells to standard chemotherapy. Therefore, it can be hypothesized that these proteins might also play a role for quercetin and lupeol.

*Protein and Vesicle Trafficking:* The translocation of proteins and vesicles to their functional sites in tumor cells has received less attention in the context of drug resistance. Impaired distribution of both cellular structures may, however, indeed influence cellular homeostasis and, therefore, contribute to carcinogenesis and differential responses to chemotherapy [130,131]. Our data obtained with lupeol, and quercetin indicate that

there is still an open field for innovative research to uncover the full range of trafficking mechanisms for responses to established cancer drugs as well as cytotoxic natural products.

*DNA/RNA Metabolism:* This is a huge field spanning many topics, such as transcription and transcription factors [132], translation [133], DNA replication [134], chromatin remodeling [135], chromosome segregation [136,137], etc. These processes are central to the vital functions of tumor cells and play important roles under the selection pressure of anticancer therapies. Understanding these mechanisms in more detail will facilitate the development of novel targeted therapies to address these mechanisms in cancer cells.

*Immune Functions:* Although tumor immunology has been a thriving field in cancer research, attention has recently focused more on the advent of passive immunotherapies (e.g., therapeutic monoclonal antibodies, immune checkpoint inhibitors) and active immunotherapeutic approaches (e.g., CAR-T). On the other hand, it is also known that the immune system influences the responsiveness of tumors to classical chemotherapy by generating therapy-resistant niches in tumors [138].

*Cytoskeleton:* Among the cytoskeletal proteins, not only the microtubules as direct targets for Vinca alkaloids, taxanes, and new drug candidates are well-known [139] but also others, such as actin, vimentin, and cytokeratin as well as proteins accompanied by cytoskeletal proteins that contribute to cytoskeletal organization and basic tumor cell features (e.g., cell remodeling during invasion and metastasis, resistance to cisplatin and other drugs, etc.) [140–142].

*Mitochondrial Functions:* Mitochondria do not only supply cancer cells with energy (in terms of ATP production) but also help them to adapt to cellular stressors, such as nutritional deprivation hypoxia and oxidative stress. Mitochondria provide sufficient biosynthetic flexibility to tumors to survive even under worse conditions [143,144]. Therefore, mitochondrial metabolism is involved in tumor progression and drug resistance [145].

*Cell Proliferation and Differentiation:* It has been long recognized that slowly growing tumors are more resistant to chemotherapy than fast-growing ones [146]. As a consequence, the cellular differentiation state, e.g., driven by the epidermal growth factor receptor (EGFR), also influences drug response [147,148]. The proteomic analyses in the present study (Table 4) indicate that several proteins involved in cellular differentiation determine sensitivity or resistance to cytotoxic natural products.

*Cell Death:* Apoptosis as most well-known mode programmed cell death is long known to affect the efficacy of chemotherapy and most other cytotoxic compounds as well [149]. However, in recent years a surprising number of non-apoptotic modes of programmed cell death have been uncovered [150]. Interestingly, these newer forms of cell death also influence the sensitivity and resistance of tumors to chemotherapy [151,152]. In the present investigation, we found that lupeol and quercetin induced necrosis rather than apoptosis. In our proteomic analyses, we also found that several proteins involved in apoptotic and non-apoptotic cell death correlated with these two natural products (Table 4).

*Ion Channels and Drug Transporters:* The membrane as the first barrier for cytotoxic compounds to enter cells represents an obvious cause of drug resistance. Though transporter molecules from the ATP-binding cassette (ABC) and solute carrier (SLC) families have been intensively studied for their role in cancer drug resistance [153,154], other membrane proteins (e.g., chloride and other ion channels) are associated with cell growth and apoptosis and, thereby, affect the response of tumor cells to chemotherapy [155]. In our own investigations during a period of more than two decades, we found that natural products are a rich source serving either as substrates and inhibitors of drug transporters and even as a new strategy to exploit hypersensitivity (collateral sensitivity) to treat otherwise drug-resistant cells [156]. Our present analysis demonstrated that channels and transporters are also involved in their responsiveness of tumor cells to natural products, such as lupeol and quercetin (Table 4).

*Cell Adhesion:* It is well known that single-cell tumors, such as leukemia, tend to respond better than solid cancer. One reason may be that solid cancers grow in tissues where the cells are connected to and communicating with each other numerous proteins

including cell adhesion molecules, integrins, adapter proteins, and associated kinases. This set of proteins has been termed “cell adhesion resistome” because these proteins contribute to anticancer drug resistance [157]. The present proteomic analyses revealed a number of proteins also belonging to this cell adhesion resistome (Table 4).

*Chaperone Functions:* Molecular chaperones are responsible for the correct folding of proteins either in the nascent state if freshly translated amino acid chains are folded to three-dimensional protein structures or if cellular stress causes misfolding and damage of proteins. These quality control mechanisms are crucial for the correct function of proteins. Chaperones, i.e., heat shock proteins, are associated with drug resistance of tumors [158–160]. We found a couple of proteins also belonging to the chaperone system to be linked with response to lupeol and quercetin (Table 4).

*Signal Transduction:* A quantity of proteins involved in signal transductions that seems to be barely manageable contribute to complex signaling networks that drive cancer cells sensitive or resistant to cancer drugs and cytotoxic natural products [161–163]. Rather than single signaling pathways, sophisticated cross-talks between different signaling routes led to broad networks determining drug response [164,165]. The new discipline of network pharmacology is just beginning to understand these complex mechanisms. This is not also true for established cancer drugs but also for natural products [166]. It will be thriving to further detect single elements in large signaling networks that are responsible for drug response of tumor cells to lupeol and quercetin in the future.

*Other Functions:* Among the proteins that do not belong to the functional categories mentioned above are DNA repair proteins, tumor suppressors, and others. Because DNA repair mechanisms as well as tumor suppressors (e.g., TP53), are well-known drug resistance mechanisms [167,168], it is also worth speculating that the proteins identified in our analyses contribute to resistance to lupeol and quercetin. It is quite unexpected to find proteins involved in melanosome biogenesis and function among the proteins correlating with quercetin responsiveness. However, because melanosomes generate ROS [169], it is possible that there is a direct or indirect link to the response of anticancer drugs. Further experiments are warranted to substantiate these findings.

In the present study, we investigated different mechanisms and targets. It became apparent that inflammation and tumor-killing properties of chamomile compounds are determined by multiple rather than by single mechanisms. The multi-specific action of chamomile and numerous other medicinal plants apparently represents a selection advantage during the evolution of plants on this globe. A large battery of defense mechanisms is superior to combat hostile organisms, such as microbes and herbivores. This principle is also realized in multi-compound pharmacology of medicinal plants. The phytotherapy relies on addressing multiple targets at the same time [58].

In the third part of the present investigation, we therefore focused on the role of NF- $\kappa$ B as prognostic factor for patient survival. Related to this topic the question of NF- $\kappa$ B as potential treatment targets for chamomile compounds addressed in the first two parts of the present study. May chamomile compounds be beneficial to prevent the onset of cancer or bypass drug resistance as additives to standard chemotherapy by inhibition of NF- $\kappa$ B? To clarify the prognostic relevance of NF- $\kappa$ B for survival of cancer patients we took advantage of the transcriptomic analyses of more than 7000 tumor biopsies derived from 21 tumor types of The Cancer Genome Atlas (TCGA) deposited at the KM-Plotter database (<https://kmplot.com/analysis/> (accessed on 20 November 2023)). We observed that renal clear cell carcinomas with low NF- $\kappa$ B expression from different patho-clinical categories (gender, grade 3, low mutation status, low neoantigen rate) were significantly correlated with longer patient survival times than tumors with high NF- $\kappa$ B expression using Kaplan-Meier statistics. These results indicate that these subgroups of tumors might benefit from NF- $\kappa$ B inhibition by chamomile compounds.

## 5. Conclusions

In conclusion, this study highlights the significant therapeutic potential of chamomile compounds, specifically  $\beta$ -amyryn, lupeol, and quercetin, in addressing inflammation and cancer. Through a thorough investigation encompassing virtual screening, experimental assays, and proteomic analyses, we have demonstrated the inhibitory effects of these compounds on NF- $\kappa$ B signaling pathways and cytokine expression. Notably, our findings suggest that chamomile derivatives could serve as promising candidates for both preventive and adjunctive cancer therapies, particularly in overcoming drug resistance mechanisms. Moving forward, further research exploring the activity of the three compounds across all inflammation pathways and conducting clinical trials are essential. This would be beneficial to fully elucidate the clinical implications and therapeutic mechanisms of chamomile compounds, paving the way for the development of novel cancer treatments and personalized medicine approaches.

## Text Correction

There was an error in the original publication [1]. A correction has been made to the **Section Results, Sub-section 3.12. Cell Death Detection**, the first two paragraphs of page. The correct terms “late apoptotic/necrotic” and “primary necrosis” have been added. Additionally, the percentage of late apoptotic/necrotic cells treated with 72 h quercetin 4×IC<sub>50</sub> and with 72 h lupeol 4×IC<sub>50</sub> have been corrected. The corrected paragraph is as follows:

“We investigated the mode of cell death in CCRF-CEM cells upon treatment with lupeol and quercetin for 72 h. The FITC-conjugated annexin V/PI assay was used to distinguish between living, early apoptotic, **late apoptotic/necrotic**, and **primary necrotic cells**. Annexin V is usually detected in early and late apoptosis. However, PI staining detects cells in late apoptosis and necrosis. Figure 10 shows that both compounds significantly induced cell death compared to the negative control. **Quercetin induced late apoptosis/necrosis in 58.70% of cells at 4×IC<sub>50</sub> (p = 0.002), while lupeol induced late apoptosis/necrosis in 73.80% of cells (p = 0.001).**”

**Copyright:** © 2021 by the authors. Submitted for possible open access publication under the terms and conditions of the Creative Commons Attribution (CC BY) license (<http://creativecommons.org/licenses/by/4.0/>).

A correction has been also made in the **Section Discussion, page 27 (paragraph 4)**. The correct term “late apoptosis/necrosis” has been corrected. The corrected paragraph is as follows:

“In this context, it was interesting that the cytotoxicity of both compounds in CCRF-CEM **late apoptosis/necrosis**. This might be a cell-type-specific effect as quercetin and lupeol have been reported to induce either apoptosis or necrosis (or necroptosis) in different cell lines [119–124]. Because apoptosis is driven by the balance of pro- and anti-apoptotic proteins in specific signaling cascades, it is known that mutations in specific genes encoding these proteins confer resistance to apoptosis [125–128]. As a consequence, cytotoxic insults may overcome apoptosis resistance by other cell death modes [129].”

## Figure/Table Legend

In the original publication [1], there was a mistake in the legends for **Figures 10**. The measurement of apoptosis was added and the legends A/C to lupeol and B/D to quercetin have been changed and the correct term “late apoptosis/necrosis” has been added. The was a slight mistake in the gating. The correct legends appear below. **As for the Figure 11 in the original publication, which presented Annexin V/PI staining results on GFP-transfected U2OS cells, is no longer considered valid. It was subsequently recognized that GFP fluorescence interfered with Annexin V-FITC detection, leading to**

signal overlap and potentially incorrect interpretation of apoptosis data. As a result, Figure 11 is being removed from the article. The corrected version of the paper will no longer include this figure. This correction does not affect the scientific conclusions of the study. The main findings remain unchanged, including: The  $IC_{50}$  values for quercetin (89.6  $\mu$ M) and lupeol (60  $\mu$ M) in U2OS cells are relatively high, indicating moderate cytotoxicity, the apoptosis assay (Annexin V/PI) was less critical for this cell line. The cell cycle analysis clearly showed  $G_2/M$  arrest, further confirming the reliability of the cytotoxicity findings. The authors apologize for any inconvenience caused and appreciate the opportunity to make this correction.

**Figure 10.** Detection of cell death in CCRF-CEM cells using flow cytometry and annexin-V/PI staining to measure apoptosis by flow cytometer. (A, B) Cells treated with  $0.25 \times IC_{50}$ ,  $0.5 \times IC_{50}$ ,  $1 \times IC_{50}$ ,  $2 \times IC_{50}$ , and  $4 \times IC_{50}$  of quercetin and lupeol, for 72 h. DMSO was used as negative control. (A) Cells treated lupeol and (B) cells treated with quercetin. Q1 represents necrotic cells (-) annexin V/(+) PI; Q2 represents late apoptotic cells exhibiting annexin V (+)/PI (+); Q3 represents early apoptotic cells (+) annexin V/(-) PI; Q4 represents viable cells (-) annexin V/(-) PI. (C, D) Bar diagrams representing the percentages of cells in the different quadrants. (C) Effects of lupeol and (D) Effects of quercetin. The treatment of both compounds at increasing concentrations significantly enhanced the percentage of necrotic cells. \*\*\*  $p < 0.001$ , \*\*  $p < 0.01$ , and \*  $p < 0.05$  compared to the negative control using paired two-tailed t-test. The bar diagrams were created the calculation of the mean values  $\pm$  SD of three independent experiments."

**Figure 11.** has been removed due to technical issues that rendered the data invalid. This correction does not affect the results or conclusions of the original article."

The authors state that the scientific conclusions are unaffected. This correction was approved by the Academic Editor. The original publication has also been updated.

#### Error in Figure/Table

In the original publication [1], there was a mistake in Figures 10 and 11 as published. The gating of the figure 10 has been correctly adjusted and figure 11 has been removed, as it was not critical to the main findings of the study and its removal does not impact the conclusions of the article.

The corrected appears below. The authors state that the scientific conclusions are unaffected. This correction was approved by the Academic Editor. The original publication has also been updated.

**Abstract:** The improvement of cancer chemotherapy remains a major challenge, and thus new drugs are urgently required to develop new treatment regimes. Curcumin, a polyphenolic antioxidant derived from the rhizome of turmeric (*Curcuma longa* L.), has undergone extensive preclinical investigations and, thereby, displayed remarkable efficacy in vitro and in vivo against cancer and other disorders. However, pharmacological limitations of curcumin stimulated the synthesis of numerous novel curcumin analogs, which need to be evaluated for their therapeutic potential. In the present study, we calculated the binding affinities of 50 curcumin derivatives to known cancer-related target proteins of curcumin, i.e., epidermal growth factor receptor (EGFR) and nuclear factor  $\kappa$ B (NF- $\kappa$ B) by using a molecular docking approach. The binding energies for EGFR were in a range of  $-12.12 (\pm 0.21)$  to  $-7.34 (\pm 0.07)$  kcal/mol and those for NF- $\kappa$ B ranged from  $-12.97 (\pm 0.47)$  to  $-6.24 (\pm 0.06)$  kcal/mol, indicating similar binding affinities of the curcumin compounds for both target proteins. The predicted receptor-ligand binding constants for EGFR and curcumin derivatives were in a range of  $0.00013 (\pm 0.00006)$  to  $3.45 (\pm 0.10)$   $\mu$ M and for NF- $\kappa$ B in a range of  $0.0004 (\pm 0.0003)$  to  $10.05 (\pm 4.03)$   $\mu$ M, indicating that the receptor-ligand binding was more stable for EGFR than for NF- $\kappa$ B. Twenty out of 50 curcumin compounds showed binding energies to NF- $\kappa$ B smaller than  $-10$  kcal/mol, while curcumin as a lead compound revealed free binding energies of  $>-10$  kcal/mol. Comparable data were obtained for EGFR: 15 out of 50 curcumin compounds were bound to EGFR with free binding energies of  $<-10$  kcal/mol, while the binding affinity of curcumin itself was  $>-10$  kcal/mol. This indicates that the derivatization of curcumin may indeed be a promising strategy to improve target specificity and to obtain more effective anticancer drug candidates. The in silico results have been exemplarily validated using microscale thermophoresis. The bioactivity has been further investigated by using resazurin cell viability assay, lactate dehydrogenase assay, flow cytometric measurement of reactive oxygen species, and annexin V/propidium iodide assay. In conclusion, molecular docking represents a valuable approach to facilitate and speed up the identification of novel targeted curcumin-based drugs to treat cancer.

## 1. Introduction

Cancer is currently one of the leading causes of death worldwide. Incidence and death rates are increasing for several types of cancer [1,2]. More than 21 million cancer incidences have been predicted to occur in the year 2025 (<https://www.statista.com/statistics/1031316/new-cancer-cases-forecast-worldwide/>; accessed on 1 March 2022). Many advances have been made in the early diagnosis and treatment of cancer. However, lowering cancer mortality rates still remains a vital challenge [3]. Cancer chemotherapy involves using natural or synthetic chemicals to prevent or suppress cancer growth. As a matter of fact, more than half of all available anticancer drugs are derivatives of natural products or are compounds that mimic the modes of action of natural products [4]. The advantages of phytochemicals are their lower toxicity profiles and their ability to target multiple signaling pathways that prevent the rapid development of drug resistance [5–7]. A number of phytochemicals are known to address cancer-related target proteins, such as the epidermal growth factor receptor (EGFR) [8–11] or the nuclear factor-kappa B (NF- $\kappa$ B) [12–14] and others.

Curcumin is a naturally occurring compound derived from the rhizomes of *Curcuma longa* L. As a member of the ginger family, it has been commonly used as a spice for food preservation as well as in folk medicine. It possesses a wide array of functional characteristics, including antioxidant and anti-inflammatory [15] as well as antiviral, antibacterial, and antifungal properties [16]. Curcumin has been extensively investigated for its cellular and molecular modes of action against cancer [17,18], diabetes [19], neurological ailments [20], and osteoarthritis [21], and even entered several clinical trials [22,23]. Curcumin inhibits cancer cell proliferation [24,25], DNA repair along the p53-p21/GADD45A-cyclin/CDK-Rb/E2F-DNMT1 axis [26,27], metastasis by the NF- $\kappa$ B/c-JUN/MMP pathway [28], and the CXC-chemokine/NF- $\kappa$ B signaling pathway [29–31] as well as angiogenesis by the protein kinase C/NF- $\kappa$ B/AP-1 pathway [32,33]. EGFR is upregulated in several tumor types, including lung and colorectal tumors making EGFR an exquisite therapeutic target. Curcumin targets EGFR in lung cancer [34,35] and colorectal carcinoma [36,37] types leading to tumor cell killing. The transcription factor NF- $\kappa$ B is targeted by curcumin in a wide range of tumor types, including leukemia and lymphoma [38–42].

In contrast to conventional anticancer drugs that often exert severe side effects such as myelosuppression, mucositis, alopecia, nausea, vomiting, and others, curcumin displays only minimal toxicity [43–45]. However, the poor bioavailability of curcumin represents a major disadvantage for its clinical application [46]. Many efforts have been undertaken to improve its bioavailability using a variety of approaches, including innovative drug delivery systems (nanoparticles, liposomes, phospholipids, etc.) as well as the development of novel synthetic curcumin derivatives [47–51]. By synthesizing chemical libraries of curcumin derivatives and subjecting them to biological scrutiny, compounds with improved pharmacological features may be yielded.

Our study focuses on curcumin and a total of 50 curcumin compounds that were either reported by us [17] or mined in the PubChem database (<https://pubchem.ncbi.nlm.nih.gov/>; accessed on 31 October 2021). We attempted to predict their activity using an in silico molecular docking approach. For this reason, we calculated the binding energies of these derivatives to two cancer-related proteins, i.e., EGFR and NF- $\kappa$ B. These proteins have been previously described as target proteins of curcumin [52].

The epidermal growth factor receptor (EGFR) is a tyrosine kinase in the cell membrane of many tumor types. This transmembrane receptor belongs to a gene family with three other members (HER2-4). The binding of extracellular ligands, i.e., epidermal growth factor (EGF) and transforming growth factor (TGF $\alpha$ ), leads to dimerization, autophosphorylation,

and downstream activation of signal transduction pathways. This ultimately leads to carcinogenesis, cell growth, metastasis, and inhibition of apoptosis [53], as well as the development of resistance to cytotoxic chemotherapy and radiotherapy [54]. Targeted therapies with small molecules (e.g., erlotinib, gefitinib, afatinib) or monoclonal antibodies (e.g., cetuximab, panitumumab) have significantly improved the treatment outcome of innumerable patients [55]. However, resistance to these targeted drugs has been emerging [56,57]. Thus, the search for new EGFR inhibitors has to continue [58]. In this context, phytochemicals gained interest as novel lead compounds [59].

The nuclear factor 'kappa-light-chain-enhancer' of activated B-cells (NF- $\kappa$ B) is a transcription factor that binds to specific DNA sequences (the 10 bp long  $\kappa$ B motif) and thereby regulates the expression of downstream genes. This primarily involves genes that control the immune response, inflammation, cell proliferation, and apoptosis [60,61]. Since NF- $\kappa$ B activation is important for cancer development and progression [62], this transcription factor has become a target molecule for new drug development [63,64]. Phytochemicals represent an important reservoir for the identification of NF- $\kappa$ B inhibitors in cancer [65–67]. Interestingly, EGFR and NF- $\kappa$ B cooperate in tumor cells, amplifying their oncogenic signals [68]. Therefore, it is particularly useful to investigate inhibitors that inhibit both cancer-related proteins simultaneously to achieve a more effective antitumor effect.

The concept of the present investigation was to identify curcumin derivatives with better binding affinities to EGFR and NF- $\kappa$ B to improve tumor specificity and reduce side effects on normal organs. To validate the molecular docking data, we exemplarily tested the inhibitory effect of curcumin and two of the derivatives investigated by western blot experiments with these four proteins towards EGFR and NF- $\kappa$ B. Our results support the concept that novel synthetic curcumin derivatives with improved specificity to important cancer-related targets could be identified by combined *in silico*–*in vitro* drug screening approaches.

## 2. Results

### 2.1. Molecular Docking

We first performed molecular docking of 50 curcumin compounds (Figure S1) mined from the PubChem database (<https://pubchem.ncbi.nlm.nih.gov/>; accessed on 31 October 2021) against EGFR and NF- $\kappa$ B. We intended to predict the potential activity of the synthetic derivatives by calculating their *in silico* binding activities to these proteins. It is noteworthy that the synthetic curcumin derivatives showed low binding energy values (i.e., higher affinities) to both target proteins.

The binding energies for EGFR were in a range of  $-12.12 (\pm 0.21)$  to  $-7.34 (\pm 0.07)$  kcal/mol and those for NF- $\kappa$ B ranged from  $-12.97 (\pm 0.47)$  to  $-6.24 (\pm 0.06)$  kcal/mol, indicating similar binding affinities of the curcumin compounds for both target proteins (Table 1). Molecular dockings of curcumin and two selected curcumin derivatives to EGFR are shown in Figure 1. The three compounds were bound to the same domain but with different amino acids within this pharmacophore.

The predicted receptor-ligand binding constants for EGFR and curcumin derivatives were in a range of  $0.00013 (\pm 0.0006)$  to  $3.45 (\pm 0.10)$   $\mu$ M and for NF- $\kappa$ B in a range of  $0.0004 (\pm 0.0003)$  to  $10.05 (\pm 4.03)$   $\mu$ M, indicating that the receptor-ligand binding was more stable for EGFR than for NF- $\kappa$ B (Table 1). Molecular dockings of curcumin and two selected curcumin derivatives to NF- $\kappa$ B are shown in Figure 2. Like EGFR, the three compounds were bound to the same domain of NF- $\kappa$ B.

**Figure 1.** Molecular docking of curcumin-type compounds to EGFR. Top: The compounds were bound to the same domain of EGFR. Bottom: curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and the derivative 1A9 were bound to different amino acids in this domain. The red circle indicates the binding site of the three compounds.

**Figure 2.** Molecular docking of curcumin-type compounds to NF-κB. Top: The compounds were bound to the same domain of EGFR. Bottom: curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and the derivative 1A9 were bound to different amino acids in this domain. The red circle indicates the binding site of the three compounds.

**Table 1.** Mean binding energies and predicted binding constants were obtained by molecular docking for 50 curcumin compounds. Dockings were independently carried out three times with every 250,000 runs (mean values  $\pm$  SD).

| Compounds  | EGFR (Mean Binding Energy, kcal/mol) | EGFR (Mean pKi, $\mu$ M) | NF- $\kappa$ B (Mean Binding Energy, kcal/mol) | NF- $\kappa$ B (Mean pKi, $\mu$ M) |

As a next step, we correlated the binding energies of the compounds for EGFR and NF- $\kappa$ B. By using Pearson correlation test, we found statistically significant relationships between binding energies and predicted inhibition constants of EGFR ( $p = 2.73 \times 10^{-9}$ ;  $r = 0.715$ ) and of ( $p = 4.39 \times 10^{-7}$ ;  $r = 0.631$ ) as well as of binding energies between EGFR and NF- $\kappa$ B ( $p = 4.32 \times 10^{-5}$ ;  $r = 0.526$ ) and predicted binding energies between both proteins ( $p = 2.53 \times 10^{-8}$ ;  $r = 0.682$ ). These results indicate that there may be a relationship between the “druggability” of the compounds being EGFR or NF- $\kappa$ B inhibitors. Compounds that were better bound to EGFR also showed a significant relationship to better bind to NF- $\kappa$ B and vice versa (Figure 3).

**Figure 3.** Correlation of binding energies (kcal/mol) and predicted inhibition constants (pKi,  $\mu\text{M}$ ) of 50 curcumin compounds were calculated using the Pearson correlation test. Correlation of binding energies and pKi values for (A) EGFR and (B) NF- $\kappa$ B. Correlation of (C) binding energies or (D) pKi values between EGFR and NF- $\kappa$ B.

## 2.2. Microscale Thermophoresis

To verify the *in silico* predictions, we performed microscale thermophoresis. This is a biophysical assay to study the interactions between chemical ligands and their target proteins. For this reason, we used recombinant EGFR and NF- $\kappa$ B and assayed them with curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and curcumin derivative 1A9. The equilibrium constants ( $K_D$ ) indicate that the three curcumin-type compounds were bound to EGFR and NF- $\kappa$ B (Figure 4).

**Figure 4.** Analysis of the interaction between curcumin derivatives with recombinant EGFR and NF- $\kappa$ B by microscale thermophoresis (MST). The recombinant proteins were used at a concentration of 200 nM, while the concentration of curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and the curcumin derivative 1A9 ranged from 100 to 100,000 nM. The migration of the fluorescent proteins was determined upon local heating using a Monolith NT.115<sup>Pico</sup> with 40% LED power and 80% MST power for EGFR and with 20% LED power and 20% MST power for NF- $\kappa$ B at room temperature.

### 2.3. Resazurin Assay

To study the effect of selected compounds on cell viability, we treated human CCRF-CEM leukemia and human A549 lung cancer cells with curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and the curcumin derivative 1A9. CCRF-CEM and A549 cells were chosen as examples of hematopoietic and solid tumor cells. Peripheral blood mononuclear cells (PBMCs) were isolated from a healthy subject to compare the inhibitory effects of the curcumin compounds between tumor and normal cells. As shown in Figure 5, all three compounds inhibited the viability of CCRF-CEM and A549 cells in a dose-dependent manner, while normal PBMCs were not or only minimally inhibited. The dose-response curves were taken to calculate the 50% inhibition concentrations ( $IC_{50}$ ). CCRF-CEM leukemia cells were about one order of magnitude more sensitive to the compounds than A549 cells and *N*-(3-nitrophenylpyrazole) curcumin revealed a higher inhibitory activity than the other two compounds (Table 2).

**Table 2.**  $IC_{50}$  values of CCRF-CEM leukemia and A549 lung carcinoma cells treated with curcumin, 1A9, and *N*-(3-nitrophenylpyrazole) curcumin as determined by the resazurin assay. The  $IC_{50}$  values ( $\mu$ M) were calculated from the dose-response curves shown in Figure 5. DMSO was used as vehicle control. Mean  $\pm$  SD of three independent measurements.

| Cells    | Compounds      |  |                |
|----------|----------------|--|----------------|
|          | Curcumin       | <i>N</i> -(3-Nitrophenylpyrazole) Curcumin | 1A9            |
| CCRF-CEM | 3.0 $\pm$ 0.4  | 1.9 $\pm$ 0.4                              | 2.6 $\pm$ 0.3  |
| A549     | 29.4 $\pm$ 1.9 | 18.9 $\pm$ 1.4                             | 23.3 $\pm$ 1.2 |
| PBMC     | >100           | >100                                       | >100           |

**Figure 5.** Cell viability dose-response curves of CCRF-CEM leukemia cells, A549 lung carcinoma cells, and healthy peripheral blood mononuclear cells treated with curcumin, 1A9, and *N*-(3-nitrophenylpyrazole) curcumin as determined by the resazurin assay. Cells were incubated with concentrations from  $10^{-3}$  to 100  $\mu\text{M}$  and incubated at 37 °C for 72 h. DMSO was used as vehicle control. Mean  $\pm$  SD of three independent measurements.

#### 2.4. LDH Assay

To assess the cytotoxicity, the LDH cell death assay was performed that measures the release of LDH from cells due to membrane damage. As shown in Figure 6, all three curcumin-type compounds led to a dose-dependent LDH release in a concentration range of 0.01 to 10  $\mu\text{M}$  in CCRF-CEM leukemia cells. Only negligible LDH release was found in healthy peripheral blood mononuclear cells, indicating tumor-specific cytotoxic effects of the three curcumin compounds.

**Figure 6.** Cytotoxicity in CCRF-CEM leukemia cells (left) and peripheral blood mononuclear cells (PBMCs) of a healthy donor (right) by curcumin, 1A9, and *N*-(3-nitrophenylpyrazole) curcumin as determined by the release of lactate dehydrogenase. Cells were incubated with concentrations from 0.01 to 10  $\mu\text{M}$  and incubated at 37 °C for 48 h. DMSO was used as vehicle control. Mean  $\pm$  SD of three independent measurements.

#### 2.5. ROS Assay

The generation of reactive oxygen species (ROS) upon exposure of CCRF-CEM cells with *N*-(3-nitrophenylpyrazole) curcumin or 1A9 was compared with the ROS generation by curcumin. As shown in Figure 7, dose-dependent effects were observed with 0.5 $\times$ , 1 $\times$ , and 2 $\times$   $\text{IC}_{50}$  concentrations of these three compounds. The strongest ROS generation was measured with 1A9, the lowest one with *N*-(3-nitrophenylpyrazole) curcumin. Curcumin produced intermediate ROS amounts.

**Figure 7.** Generation of reactive oxygen species in CCRF-CEM cells by curcumin, *N*-(3-nitrophenylpyrazole) curcumin, and 1A9. Cells were incubated with 0.5×, 1×, 2×, or 4× IC<sub>50</sub> and incubated at 37 °C for 24 h. DMSO was used as vehicle control. Mean ± SD of three independent measurements.

#### 2.6. Annexin/PI Assay

The induction of early and late apoptosis by the three curcumin compounds was determined by the annexin V/propidium iodide assay and flow cytometry. Incubation of CCRF-CEM cells at 37 °C for 24 h showed clear dose-dependent induction either of early or late apoptosis in a concentration range from 0.5× to 4× IC<sub>50</sub> (Figure 8). The effects of 1A9 were even stronger: the highest fraction of apoptotic cells was observed already at the lowest concentration of 0.5× IC<sub>50</sub>. Higher concentrations led to a decrease in early apoptotic cells and an increase in late apoptotic cells, indicating a concentration-dependent switch from early to late apoptosis upon exposure with 1A9 at 37 °C for 24 h (Figure 8). Although *N*-(3-nitrophenylpyrazole) curcumin was cytotoxic in the LDH assay and inhibited viability in the resazurin assay, it did not induce early or late apoptosis after 24 h incubation (Figure 8). Even after prolonged incubation at 37 °C for 48 or 72 h, *N*-(3-nitrophenylpyrazole) curcumin did not induce apoptosis (Figure 9). The low percentages of apoptosis cells did not exceed the low rates of spontaneous apoptosis in DMSO-treated control cells.

**Figure 8.** Induction of apoptosis in CCRF-CEM cells upon exposure at 37 °C for 24 h with curcumin, N-(3-nitrophenylpyrazole) curcumin, and 1A9 as determined by the annexin V/propidium iodide assay and flow cytometry. Cells were incubated with 0.5 ×, 1 ×, 2 ×, or 4 × IC<sub>50</sub>. DMSO was used as vehicle control. Mean ± SD of three independent measurements.

**Figure 9.** Cont.

**Figure 9.** Induction of apoptosis in CCRF-CEM cells upon exposure at 37 °C for 48 or 72 h with *N*-(3-nitrophenylpyrazole) curcumin as determined by the annexin V/propidium iodide assay and flow cytometry. Cells were incubated with 0.5×, 1×, 2×, or 4× IC<sub>50</sub> *N*-(3-nitrophenylpyrazole) curcumin. Positive control: curcumin (4× IC<sub>50</sub>); negative control: DMSO. Mean ± SD of three independent measurements.

### 3. Discussion

In the present study, we investigated the *in silico* binding affinities of a total of 50 curcumin compounds to EGFR and NF- $\kappa$ B. The aim was to find novel derivatives with improved binding properties to these two cancer-related proteins as a starting point to develop curcumin-based drugs with improved pharmacological features.

EGFR plays a central role in the pathogenesis and progression of different carcinoma types. EGFR is overexpressed in many human carcinomas and is also involved in developing resistance to chemotherapy [54,56]. On average, 50–70% of lung, colon, and breast carcinoma express EGFR [69]. Inhibition of EGFR phosphorylation is caused by directly inhibitor effects of curcumin on the tyrosine kinase activity of EGFR as well as by curcumin-induced alterations of the physical plasma membrane properties influencing receptor dimerization [70]. Additionally, curcumin downregulated EGFR protein expression [36].

From previous investigations on the activity of curcumin derivatives towards EGFR [71], it is known that substitutions on the phenyl rings affected the extent of EGFR down-regulation. Moreover, methoxy or hydroxy substituents increased the compounds' activity, while other alkyloxy groups did not. The activity was, in general, not influenced by methoxy, hydroxy, or halogen groups. Remarkably, *N*-(3-nitrophenylpyrazole) curcumin was bound better to EGFR than the halogenated curcumin derivatives investigated in this study, including difluorinated curcumin that is frequently described in the literature as a promising drug candidate for further drug development [72].

NF- $\kappa$ B regulates the expression of genes involved in many processes that play a key role in cancer biology, such as proliferation, migration, and apoptosis. NF- $\kappa$ B influences the expression of genes that are involved in a large number of physiological processes, including immune response, cell survival, differentiation, and proliferation. Curcumin has been described as a potent inhibitor of NF- $\kappa$ B activation [73]. Twenty out of 50 curcumin compounds showed binding energies to NF- $\kappa$ B smaller than  $-10$  kcal/mol, while curcumin as a lead compound revealed free binding energies of  $>-10$  kcal/mol. Comparable data

were obtained for EGFR: 15 out of 50 curcumin compounds were bound to EGFR with free binding energies of  $< -10$  kcal/mol, while the binding affinity of curcumin itself was  $> -10$  kcal/mol. This indicates that the derivatization of curcumin may indeed be a promising strategy to improve target specificity and to obtain more effective anticancer drug candidates.

Even though *N*-(3-nitrophenylpyrazole) curcumin was bound to EGFR and NF- $\kappa$ B, it inhibited cell viability (as shown by the resazurin assay) and was cytotoxic (as shown by the LDH assay) in a comparable manner as curcumin and 1A9. *N*-(3-nitrophenylpyrazole) curcumin did not induce ROS generation and did not induce apoptosis. This indicates that different curcumin derivatives may activate different downstream mechanisms despite identical upstream targets (EGFR, NF- $\kappa$ B). *N*-(3-nitrophenylpyrazole) curcumin apparently induced a ROS-independent non-apoptotic pathway of cell death. This is a novel finding that may have important therapeutic implications. It is well-known that tumor cells with defective apoptotic regulation exert resistance to the induction of cell death, resulting in tumor progression and resistance to anticancer drugs [74,75]. Having cytotoxic drugs at hand, such as *N*-(3-nitrophenylpyrazole) curcumin, may allow one to bypass apoptosis resistance and kill otherwise apoptosis-resistant tumors. It is now well-known that a plethora of different cell death mechanisms can be operative in tumor cells [76,77]. It is beyond the scope of the present investigation to clarify which alternative mechanisms of cell death are responsible for the cytotoxic activity of *N*-(3-nitrophenylpyrazole) curcumin. We will address this issue in the future.

## 4. Materials and Methods

### 4.1. Chemicals

Chemical structures for *in silico* analyses were downloaded from PubChem (<https://pubchem.ncbi.nlm.nih.gov/>; accessed on 31 October 2021). Curcumin and DMSO were of analytical grade and purchased from Sigma-Aldrich (Taufkirchen, Germany). The curcumin derivative 1A9 was synthesized as recently reported [17]. *N*-(3-nitrophenylpyrazole) curcumin was provided by Dr. Fadhil S. Kamounah (Department of Chemistry, University of Copenhagen, Denmark). Stock solutions (50 mM) were prepared in DMSO, stored at  $-20$  °C, and diluted to the final concentration in fresh media before each experiment. The chemical structures of 50 curcumin compounds are shown in Supplementary Figure S1.

### 4.2. Docking

The X-ray crystallography-based three-dimensional protein structures of EGFR and NF- $\kappa$ B (PDB codes 1M17 and 1VKX, respectively) were obtained from the RCSB Protein Data Bank (<http://www.rcsb.org/pdb/home/home.do>; accessed on 31 October 2021) and used as docking templates throughout the calculations. Two-dimensional structures of curcumin and its derivatives were energy-minimized and converted to 3D structures compatible for docking operation using the Chem 3D program. Molecular docking was then carried out with the AutoDock program 4.2.6 (The Scripps Research Institute, La Jolla, CA, USA) following a previously reported protocol [78,79]. Docking parameters were set to 250 runs and 250,000 energy evaluations for each cycle. Three independent cycles were performed, resulting in a total number of 750,000 calculations per compound and target protein. VMD (Visual Molecular Dynamics, Visual Molecular Dynamics, <http://www.ks.uiuc.edu/Research/vmd/>; accessed on 31 October 2021) was used as a visualization tool to illustrate further the binding modes obtained from docking.

### 4.3. Microscale Thermophoresis

*In vitro* protein binding assays were performed to validate the *in silico* interaction between EGFR and NF- $\kappa$ B). The recombinant proteins were obtained from commercial sources (EGFR cat. No. 10001-H08H, NF- $\kappa$ B cat. No. 12054-H09E, Sino Biological Europe GmbH, Eschborn, Germany). The proteins were labeled according to the Monolith™ NT.115 Protein Labeling Kit RED-NHS (NanoTemper Technologies GmbH, Munich, Ger-

many). Varying concentrations of curcumin, *N*-(3-phenylpyrazole) curcumin, and the curcumin derivative 1A9 ranging from 100 to 100,000 nM were titrated with labeled EGFR or NF- $\kappa$ B. As previously described, the experiments were carried out using standard capillaries in the NanoTemper Monolith™ NT (NanoTemper Technologies GmbH, Munich, Germany) [80,81]. Microscale thermophoresis (MST) was performed with 40% LED power and 80% MST power for the labeled EGFR and with 20% LED power and 20% MST power for the labeled NF- $\kappa$ B.

#### 4.4. Cell Culture

The A549 lung cancer cell line was obtained from the German Cancer Research Center (DKFZ, Heidelberg, Germany). The original source of the cell lines is the American Type Culture Collection (ATCC, Manassas, VA, USA). The cells were cultivated in a completed DMEM culture medium with GlutaMAX (Invitrogen, Germany) supplemented with 10% fetal bovine serum, l-glutamine (2 mM), and 1% of a 10,000 U/mL penicillin G and 10 mg/mL streptomycin at 37 °C in a humidified air incubator (95%) containing 5% CO<sub>2</sub>. All experiments were performed on cells in the logarithmic growth phase. CCRF-CEM cells were a gift from Dr. Axel Sauerbrey (University Hospital for Pediatrics, University of Jena, Germany) and maintained in an RPMI medium supplemented with fetal bovine serum, glutamine, and penicillin as described above.

Peripheral blood from healthy donors was obtained from Transfusion Center (University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany). Human peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation using Histopaque-1077® (Sigma-Aldrich Co. LLC, Darmstadt, Germany), strictly following the manufacturer's instructions. Isolated PBMCs were resuspended in warm Panserin 413 medium (PAN-Biotech, Aidenbach, Germany) supplemented with 2% phytohemagglutinin M (PHA-M, Life Technologies, Darmstadt, Germany) and then immediately used for experimentation.

#### 4.5. Resazurin Cell Viability Assay

Viable cells reduce the non-fluorescent resazurin to the strongly-fluorescent resorufin. Suspension cells ( $1 \times 10^4$  cells/well) or adherent cells ( $5 \times 10^3$  cells/well, incubated overnight to allow attachment) were seeded in 96-well plates at a volume of 100  $\mu$ L. Varying concentrations of curcumin, 1A9, or *N*-(3-nitrophenylpyrazole) curcumin were added to reach a total volume of 200  $\mu$ L. After 72 h, 20  $\mu$ L of 0.01% *w/v* resazurin (Sigma-Aldrich) was added to each well, and cells were incubated for another 4 h at 37 °C. The fluorescence of resorufin was measured at 544 nm (excitation) and 590 nm (emission) using an Infinite M2000 Pro™ plate reader (Tecan, Crailsheim, Germany). Each experiment was independently performed three times with six parallel measurements each. The effects on cell viability were assessed according to the percentage of untreated control and 50% inhibition concentrations (IC<sub>50</sub>) were calculated from dose-response curves using GraphPad Prism® v6.0 software (GraphPad Software Inc., San Diego, CA, USA).

#### 4.6. Lactate Dehydrogenase (LDH) Assay

The LDH release from the cells was determined using an LDH-cytotoxicity assay kit (catalog no. ab65393, Abcam, Berlin, Germany). CEM/CCRF leukemia cells and peripheral blood mononuclear cells (PBMCs) were seeded in 96-well plates at a density of  $4 \times 10^4$  cells/well. Varying concentrations ranging from 0.01 to 10  $\mu$ M of curcumin, *N*-(3-nitrophenylpyrazole) curcumin, or 1A9 were added to the cells and incubated for 48 h. At the end of the incubation period, the plates were gently shaken to ensure LDH was evenly distributed in the culture medium. Afterward, cells were precipitated at  $600 \times g$  for 10 min and 10  $\mu$ L/well of the clear supernatant medium were transferred to optically clear 96-well plates. The LDH reaction mix (100  $\mu$ L/well) was added and incubated for 30 min at room temperature. The absorbance of LDH was measured with an Infinite M2000 Pro™ plate reader (Tecan, Crailsheim, Germany) using a 450 (440–490) nm filter.

#### 4.7. Reactive Oxygen Species (ROS) Detection Assay

Intracellular reactive oxygen species (ROS) were determined using the cellular reactive oxygen species detection assay kit (catalog No. ab186027, Abcam, Berlin, Germany). Briefly,  $4 \times 10^4$  CEM/CCRF leukemia cells/well were seeded in 96-well plates and incubated with 100  $\mu$ L/well of ROS red working solution for 1 h in an incubator at 37 °C in a 5% CO<sub>2</sub> atmosphere. Afterward, cells were treated with curcumin, *N*-(3-nitrophenylpyrazole) curcumin, or 1A9. For each compound, varying concentrations ( $0.5 \times IC_{50}$ ,  $IC_{50}$ ,  $2 \times IC_{50}$ ) were used. After incubation for 24 h, the ROS induction was monitored at Ex/Em = 520/605 nm using an Infinite M2000 Pro™ plate reader (Tecan, Crailsheim, Germany).

#### 4.8. Annexin V/Propidium Iodide (PI) Assay

CCRF-CEM cells ( $1 \times 10^6$  cells/mL) were seeded in 6-well plates and different concentrations of curcumin, 1A9, or *N*-(3-nitrophenylpyrazole) curcumin ( $0.5 \times$ ,  $1 \times$ ,  $2 \times$ ,  $4 \times IC_{50}$ ) were applied at 37 °C for 24 h. The cells were washed and re-suspended in 1 mL cold PBS and 500  $\mu$ L  $1 \times$  binding buffer, respectively, followed by incubation with 5  $\mu$ L annexin V/PI and 10  $\mu$ L of PE (50 mg/mL) (Thermo Fisher Scientific, Dreieich, Germany) in the dark for 15 min. The histograms were measured using an Accuri C6 flow cytometer (Becton Dickinson, Heidelberg, Germany). Four different cell populations were determined: viable cells, annexin V positive/PI negative cells (cells that are in early apoptosis), annexin V negative/PI-positive cells (cells that are necrotic), and annexin V positive/PI-positive cells (cells that are in late apoptosis or already dead).

## 5. Conclusions

In conclusion, we speculated that synthetic derivatives bear potential for cancer treatment, especially as EGFR inhibitors. Some synthetic derivatives are bound to and inhibit their target proteins in a comparable or even better manner than their parent lead compound, curcumin. The chemistry of curcumins is a fascinating area of research. It should be kept in mind that curcumin is not only active against cancer but also against many diseases such as metabolic syndrome, ulcerative colitis and inflammatory diseases in general, neurodegenerative diseases, infectious diseases, etc. [82–86]. It is well in the scope of expectations that some of the curcumin derivatives described in the present study may also be valuable drug candidates for other diseases than cancer. We believe they may be valuable candidates in the further drug discovery process.

## BERUFSERFAHRUNG

### **Doktorandin**

**09/2018 - vsl. 2025**

*Johannes Gutenberg-Universität Mainz, Mainz*

Erfahrung in Zellkultur, Zytotoxizitätstests, Funktionsassays, Western Blot, qRT-PCR, Immunhistochemie, Immunofluoreszenz, Durchflusszytometrie, Molekulardocking, Virtual Drug Screening, Microscale Thermophoresis; Projekt Management und Team Arbeit; zudem Leitung und Betreuung von Praktikanten, Koordination von Praktikumsaktivitäten und Betreuung der Studierenden bei Projekten sowie deren Weiterentwicklung. Co-Autorin in einem klinischen Forschungsprojekt mit Verantwortung für die Datenkuratierung und Dokumentation von Patienten\*

### **Managing Editor**

**01/2022 - 12/2024**

*Phytomedicine, Elsevier GmbH*

Verwaltung des Redaktionsprozesses wissenschaftlicher Veröffentlichungen, Koordination von Manuskriptüberprüfungen, Sicherstellung der Einhaltung von Verlagsstandards sowie Aufrechterhaltung der Kommunikation mit Autoren

### **Studentische Hilfskraft**

**10/2019 - 03/2020**

*Deutsches Kinderkrebsregister (DKKR) Universitätsmedizin Mainz, Deutschland*

Unterstützung bei der Eingabe von Informationen in Datenbanken, Übersetzung von Korrespondenz und Materialien (Deutsch-Englisch) sowie Übernahme organisatorischer Aufgaben im Rahmen eines Symposiums

### **Praktikum im Bereich Kundenberatung**

**04/2019 - 07/2019**

*LimitSport, Mainz*

Kundenberatung. Kontakt und Koordination mit französischen Kunden.

## Zertifizierung

- Zertifikat von ICH-GCP NIDA clinical trials network
- Zertifikat von Projekt Management Institute und LinkedIn

## PUBLIKATIONEN

**ANTI-INFLAMMATORY AND CANCER PREVENTIVE POTENTIAL OF CHAMO-MILE (MTRICARIA CHAMOMILLA L.): A COMPREHENSIVE IN SILICO AND IN VITRO STUDY**

Biomedecines Journal, mdpi, 2024

**COX2-INHIBITORY AND CYTOTOXIC ACTIVITIES OF PHYTOCONSTITUENTS OF MTRICARIA CHAMOMILLA L.**

Applied Sciences Journal, mdpi, 2023

**IN SILICO AND IN VITRO SCREENING OF 50 CURCUMIN COMPOUNDS AS EGFR AND NF- $\kappa$ B INHIBITORS**

International Journal of Molecular Sciences, 2022

**BIOMARKER PROFILING REVEALED CARCINOEMBRYONIC ANTIGEN AS A TARGET OF ARTESUNATE IN A DUCTAL BREAST CANCER PATIENT\***

Anticancer research, 2022

**IDENTIFICATION OF ACTIVE COMPONENTS IN ANDROGRAPHIS PANICULATA TARGETING ON CD81 IN ESOPHAGEAL CANCER IN VITRO AND IN VIVO**

Phytomedicine Journal, 2022

**IDENTIFICATION OF GEDUNIN FROM A PHYTOCHEMICAL DEPOSITORY AS A NOVEL MULTIDRUG RESISTANCE-BYPASSING TUBULIN INHIBITOR OF CANCER CELLS**

Molecules Journal, 2022

## Konferenzen/Präsentationen

**Young Presenter**

09/2020

World Cancer Congress (Lisbon, Portugal)

Präsentation zum Thema COX2-Inhibitory and Cytotoxic Activities of Phytoconstituents of Matricaria chamomilla L.

**Praktikantin**

07/2014 - 08/2014

*CHU Mustapha Alger, Algier*

Abteilung Onkologie: Vorbereitung von Blutproben zur Analyse und Assistenz der Laborbiologen während des Analyseprozesses

**Praktikantin**

07/2013 - 07/2013

*CHU Mustapha Alger, Algier*

Abteilung Onkologie: Vorbereitung von Blutproben zur Analyse und Assistenz der Laborbiologen während des Analyseprozesses

## BILDUNGSWEG

**Ph.D. Pharmazie und Biomedizin**

11/2018 - vsl. 2025

*Johannes Gutenberg University Mainz am Institut für Pharmazie und Biomedizin. Abteilung für Pharmazeutische Biologie*

Schwerpunkte: Entzündungshemmung und Krebsprävention mit Naturstoffen; Doktorarbeit zum Thema ‚The Effect of Chamomile and Curcumin Compounds Against Inflammation and Cancer‘

**M.Sc. Biotechnologie und Pflanzenwissenschaft**

09/2014 - 06/2016

*Université des Sciences et de la Technologie Houari (Algier)*

Schwerpunkte: Biotechnologie und Pflanzenwissenschaften; Masterarbeit zum Thema ‚Biosystematische Untersuchung der Gattung Bellevalia der Hyacinthaceae‘

**B.Sc. Biologie, Physiologie und Pflanzengenetik**

09/2011 - 06/2014

*Université des Sciences et de la Technologie Houari (Algier)*

Schwerpunkte: Biologie, Physiologie und Pflanzengenetik; Bachelorarbeit zum Thema ‚Wirkung von Salicylsäure und Stress auf Bohnenpflanzen (Phaseolus vulgaris)‘

**Abitur (Baccalaureat)**

09/2010 - 06/2011

*Saint-Elizabeth-Gymnasium (Algier)*

Schwerpunkt: Naturwissenschaft

## WEITERBILDUNG

**Deutsche Sprachschulung von Level A1 bis C1**

01/2017 - 04/2018
