Abstract

Pancreatic neuroendocrine tumors (panNETs) are a rare malignancy that is difficult to treat. Since a considerable number of panNETs exhibit high mTOR pathway activity, current therapeutic strategies for advanced panNETs often involve the use of mTOR inhibitors. Recently, there has been discussion regarding the potential benefits of combining mTOR inhibition with therapies targeting cellular metabolism. These are based on observations that mTOR signalling also impacts mitochondrial functions and the expression of nuclear-encoded mitochondria-related genes. However, the precise interaction between mTOR and mitochondrial function, particularly in the context of panNETs, remains poorly understood. Consequently, the objective of this study is to identify proteins that connect these two systems and assess the functional implications of this relationship.

In the present study, a well-characterized cohort of 157 panNETs was established. We identified pS6 as a reliable biomarker for the mTOR pathway activity in panNET, as we revealed that 22 % of the investigated panNET exhibit mTOR pathway activity by expression analysis of pS6. We could verify this finding by identifying the mTORc1 pathway as the most upregulated pathway in panNET with activated mTOR pathway using RNA-sequencing and gene set enrichment analysis (GSEA). In addition, we were able to identify two mitochondria related proteins as targets of mTOR in panNET. RNA sequencing of panNET tissue and cell lines highlighted PGC1 α as the most significantly upregulated gene in tumors with activated mTOR and in the BON1 cell line control group that was compared to BON1 cells treated with mTOR inhibitors. Furthermore, mortalin was found to be highly upregulated in high-grade panNETs with elevated mTOR activity. Interestingly, PGC1 α was shown to influence mTOR pathway activity, while mortalin did not impact mTOR signaling. We could not find any correlation between somatic mutations in the mitochondrial DNA and the mTOR pathway activity

In summary, these findings offer valuable insights into the molecular interactions between mTOR signalling and the mitochondria-related proteins mortalin and PGC1 α in panNETs. This may pave the way for new treatment options for this rare tumor entity, offering benefits for patients.

Zusammenfassung

Pankreatische neuroendokrine Tumore (panNETs) stellen eine seltene, schwer behandelbare Krebserkrankung dar. Ein erheblicher Anteil dieser Tumoren weist eine erhöhte Aktivität des mTOR-Signalwegs auf, weshalb Inhibitoren dieses Signalwegs Teil der Therapie bei fortgeschrittenen panNETs sind. In den letzten Jahren wurde diskutiert, ob eine Kombination aus mTOR-Inhibitoren und Therapien, die den Zellstoffwechsel gezielt ansprechen, zusätzliche Vorteile bieten könnte. Diese Überlegungen basieren auf der Erkenntnis, dass der mTOR-Signalweg auch mitochondriale Funktionen und die Expression mitochondrialer nukleär kodierter Gene beeinflusst. Die genaue Wechselwirkung zwischen mTOR und mitochondrialen Faktoren, insbesondere in panNETs, ist jedoch bislang wenig erforscht. Ziel dieser Studie war es daher, Gene und Proteine zu identifizieren, die diese beiden Systeme miteinander verbinden.

In der vorliegenden Arbeit wurde eine Kohorte von 157 panNETs untersucht. pS6 wurde als zuverlässiger Biomarker für die mTOR-Aktivität identifiziert, wobei in 22 % der Tumore ein aktivierter mTOR-Signalweg nachgewiesen werden konnte. Dieses Ergebnis wurde mittels RNA-Sequenzierung und GSEA-Analyse bestätigt. Es konnte nachgewiesen werden, dass der mTORc1-Signalweg in Tumoren mit erhöhter mTOR-Aktivität der am stärksten hochregulierte Signalweg ist. Im Rahmen der RNA-Sequenzierung wurde außerdem PGC1 α als das am stärksten hochregulierte Gen in Tumoren mit aktiviertem mTOR-Signalweg identifiziert. Eine vergleichbare Hochregulation von PGC1 α zeigte sich auch in unbehandelten BON1-Zellen im Vergleich zu BON1-Zellen, die mit mTOR-Inhibitoren behandelt wurden. Zudem war Mortalin in fortgeschrittenen panNETs mit erhöhter mTOR-Aktivität stark hochreguliert. Interessanterweise konnte außerdem gezeigt werden, dass PGC1 α Einfluss auf den mTOR-Signalweg nimmt, während Mortalin keinen Einfluss zu haben scheint. Eine Korrelation zwischen somatischen Mutationen in der mitochondrialen DNA und der mTOR-Aktivität konnte nicht nachgewiesen werden. Zusammenfassend liefern diese Ergebnisse wertvolle Einblicke in die molekularen Interaktionen zwischen dem mTOR-Signalweg und mitochondrialen Proteinen, die potenziell neue therapeutische Ansätze für diese seltene Tumorform eröffnen.

1. Introduction

1.1 Neuroendocrine tumours of the pancreas (panNET)

1.1.1 The Pancreas

The pancreas is located behind the stomach in the retroperitoneal space (Fig. 1, Manser, 2013). The organ is 15 to 20 cm long and consists of three anatomical parts: the tail (*Cauda*), body (*Corpus*), and head (*Caput*) (Fig. 1, Manser, 2013). The head is connected to the duodenum via the pancreatic duct (Fig. 1, Manser, 2013). Histologically and functionally, the pancreas is divided into an exocrine and endocrine component (Schünke et al., 2018). The exocrine part of the pancreas consists of multiple glands that produce digestive enzymes (Schünke et al., 2018). These enzymes are needed for the breakdown of nutrients like carbohydrates or fats in the small intestine (Schünke et al., 2018). The endocrine component of the pancreas consists of clusters of epithelial cells known as islets of Langerhans, which are scattered along the exocrine part (Schünke et al., 2018). These epithelial cells can be divided into five different endocrine cell types that are named after the Greek alphabet (alpha, beta, delta, epsilon, upsilon; Schünke et al., 2018). These five endocrine cell types can secrete a wide variety of hormones, with insulin and glucagon being the most important ones, as they regulate blood sugar levels (Schünke et al., 2018).

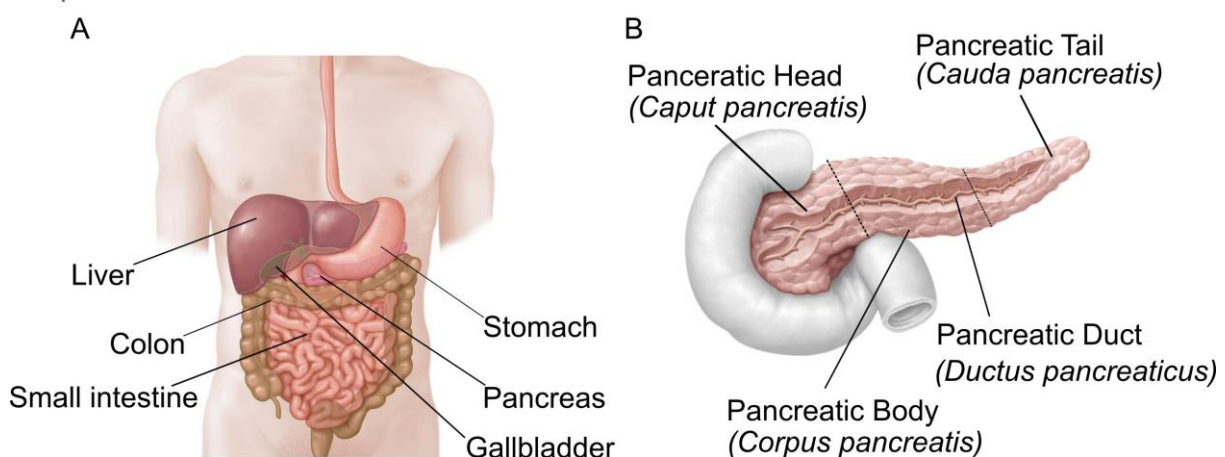

Figure 1: Localization and anatomy of the pancreas.

A) Localization of the pancreas. The pancreas is located behind the stomach, underneath the liver and above the colon in the retroperitoneal space. B) Anatomy of the pancreas. The pancreas consists of the three anatomical parts head, body and tail. (modified according to Schünke et al., 2018)

1.1.2 Epidemiology of panNET

Neuroendocrine tumours (NET) are a heterogeneous group of slowly growing cancers that arise from the diffuse neuroendocrine system (Scott & Howe, 2019; Storni et al., 2021). In comparison to other tumour entities they are rare malignancies with an incidence of about 7 per 100.000 people per year (Storni et al., 2021). NETs can be located in a variety of organs but up to 70 % occur in the gastrointestinal tract and pancreas (Maharjan et al., 2021; Oronsky et al., 2017; Storni et al., 2021). With regard to the pancreas, that means that 2 % of all tumours occurring in this organ are defined as NETs (Dasari et al., 2017). Most panNETs are sporadic but up to 10% are associated with inherited cancer syndroms like the Multiple endocrine neoplasia type 1 or the von-Hippel-Lindau syndrome (Jensen et al., 2008; Lehnert, 2015; Maharjan et al., 2021). While hereditary panNETs are more common in younger patients, sporadic panNETs are most frequently diagnosed in patients between the ages of 30 and 60 years (Lehnert, 2015). In total, the mean age at diagnosis is between 57 and 58 years without clear differences between the sexes regarding the occurrence of tumours (Greenberg et al., 2022; Scott & Howe, 2019).

1.1.3 Classification of panNET

Classification of NET is based on three categories: site of origin, proliferation index and the appearance of hormone release (Giuseppe Lamberti et al., 2018).

The proliferation index is identified by immunohistochemical staining of the proliferation marker Ki-67 according to the guidelines of the World Health Organization (WHO; Rindi et al., 2022). Based on this classification, NETs are divided into G1, G2 or G3 tumours (Table 1).

Table 1: Grading of NET according to the WHO-classification from 2019.

Grading	Ki-67 [%]
G1	< 3
G2	3 – 20
G3	> 20

In addition to this proliferation-based classification, the European Neuroendocrine Tumour Society (ENETS) and the American Joint Committee on Cancer/Union for International Cancer Control (AJCC/UICC) brought the TNM-staging system to life.

This system covers more information about the tumour, including size and extend of the primary tumour (T), the appearance of lymph node metastasis (N) and the presence of distant metastasis (M) (Table 2; Klöppel et al., 2010).

Table 2: TNM-Classification of NET.

(and Ferreira-Silva et al., 2024; modified according to Wittekind, 2017)

T (primary tumour)			
T ₀		No primary tumour	
T ₁ to T ₄		Primary tumour detected Classification according to size and extend of the primary tumour	
N (lymph node metastasis)			
N ₀		No lymph node metastasis	
N ₁ bis N ₃		Lymph node metastasis detected Classification according to localization and frequency	
M (distant metastasis)			
M ₀		No distant metastasis	
M ₁		Distant metastasis detected	
Anatomic stage			
Stage I	T ₁	N ₀	M ₀
Stage IIA	T ₂	N ₀	M ₀
Stage IIB	T ₃	N ₀	M ₀
Stage IIIA	T ₄	N ₀	M ₀
Stage IIIB	Any T	N ₁	M ₀
Stage IV	Any T	Any N	M ₁

1.1.3.1 Hormonal release and clinical symptoms of panNET

Beside the proliferation index, panNETs can be categorized according to their ability to release hormones into the surrounding tissue. They can be divided into two groups: functional and non-functional tumours. Around 60 to 90% of panNET are non-functional, which means that they can secrete hormones but in a quantity that do not trigger any specific symptoms (Guilmette & Nosé, 2019; Maharjan et al.,

2021). In contrast, functional panNET also secrete hormones but in a quantity that leads to unspecific symptoms like shortness of breath, diarrhoea and rapid heartbeat as well as hormone specific symptoms in patients (Guilmette & Nosé, 2019; Lehnert, 2015; Storni et al., 2021). The hormone specific symptoms are listed in Table 3.

Table 3: Classification of functional panNET.

(Paniccia et al., 2015)

Tumour	Hormone	Symptom	Incidence [%]
Insulinoma	Insulin	Hypoglycemic	35 - 40
Gastrinoma	Gastrin	Zollinger-Ellison syndrome	16 - 30
Glucagonoma	Glucagon	Rashes, Malfunction of the glucose balance	<10
VIPoma	Vasoactive intestinal polypeptide	Verner-Morrison-Syndrome	<10
Somatostatinoma	Somatostatin	Diabetes	<5

1.1.4 Therapy of panNET

Besides early diagnosis, effective therapy is critical for survival of patients. The only curative therapy for panNET consist of the resection of the tumour, which is mostly implemented for primary, non-metastatic tumours (Akirov et al., 2019; Ro et al., 2013; Storni et al., 2021). Systematic therapies are often used for disease control and minimization of symptoms in patients with metastases and residual disease (Maharjan et al., 2021; Scott & Howe, 2019). These therapies include so called somatostatin analogues that are mostly used in functional panNETs as they are effective against hormone production (Ro et al., 2013). Although there is no clear evidence that these analogues are beneficial for patients with non-functional panNET, they seem to suppress tumour growth in this group (Lamberts, 1988; Sidéris et al., 2012). In the last few years, inhibitors of the mechanistic Target of Rapamycin (mTOR) have become important for the therapy of panNET.

1.2 The mTOR signalling pathway

The mTOR signalling pathway is a network that integrates a wide variety of biological processes that contribute to cellular homeostasis and metabolism (Laplante & Sabatini, 2012; Panwar et al., 2023; Saxton & Sabatini, 2017). The centre of this pathway is the mTOR protein that has a dual kinase activity as it

phosphorylates serine/threonine or tyrosine kinases (Panwar et al., 2023). Moreover, the mTOR protein forms the catalytic subunit of the two functional complexes mTOR-complex1 (mTORc1) and mTOR-complex2 (mTORc2) (Liu & Sabatini, 2020; Panwar et al., 2023). The exact structure of the complexes is shown in Figure 2.

Figure 2: Structure of mTORc1 and mTORc2.

The domain structure of the catalytic subunit mTOR (in green) includes various binding sites for the subunits of mTORC1 (A) and mTORC2 (B). The catalytic subunit of mTOR consists, in both complexes, of HEAT repeats (comprising clusters of Huntingtin, the elongation factor 3, a subunit of protein phosphatase 2A, and TOR1 or TOR2), followed by a FRAP, ATM, and TRRAP (FAT) domain, as well as the FKBP12-Rapamycin-binding domain (FRB), the catalytic kinase domain, and the C-terminal FATC domain. Additionally, the structure of mTORC1 (A) includes Raptor as a defined subunit, which recruits PRAS40 (an insulin-regulated mTORC1 inhibitor). In mTORC2 (B), the additional subunits of the multiprotein complex comprise mLST8, DEPTOR, and RICTOR as defined components. Moreover, RICTOR recruits the protein associated with rictor 1 or 2 (PROTOR1/2) along with the MAPK-interacting protein (mSIN1) as scaffold proteins. (modified according to Liu & Sabatini, 2020).

Besides their slightly different composition, both complexes differ in their activation, function, and sensitivity against the mTOR-inhibitor rapamycin. While both complexes can be activated by signals from growth factors, mTORc1 mainly processes information about nutrients, hormones, amino acids and hypoxia (Tian et

al., 2019). In terms of their functions, the mTORc1 is well known for its role in the protein biosynthesis, nucleotide synthesis and the regulation of different metabolism, whereas mTORc2 regulates the organization of the cytoskeleton, cell survival and cell proliferation (W. Fu & Hall, 2020; Panwar et al., 2023; Saxton & Sabatini, 2017). It has been shown that the function of mTORc1 can be prevented by inhibition using rapamycin (Kang et al., 2013). For mTORc2 it has long been postulated that this inhibitor has no impact on its activity. Nevertheless, a study from Sarbassov *et al.* showed that extended incubation with rapamycin (up to 24 hours) can lead to inhibition of mTORc2 in a variety of carcinoma cell lines (Dos D. Sarbassov et al., 2006).

1.2.1 Downstream of mTORc1

The mTORc1 integrates stimuli from a variety of nutrients and growth factors for promotion of the synthesis of nucleotides, lipids and proteins (Saxton & Sabatini, 2017). At the same time, mTORc1 suppresses catabolic processes like autophagy (Saxton & Sabatini, 2017).

In case of the protein synthesis, the p70S6 Kinase 1 (S6K1) and eIF4E Binding Protein (4EBP1) are the two most well-known downstream targets of mTORc1. The S6K1 is directly phosphorylated by mTORc1 at T389, leading to phosphorylation of the ribosomal protein S6 (S6), a component of the 40S subunit of ribosomes (Dennis et al., 1998; Meyuhas, 2015). The S6 protein then activates different targets that are involved in mRNA translation initiation, leading to increased protein synthesis (Holz et al., 2021; Saxton & Sabatini, 2017). The second downstream target of mTORc1, 4EBP1, promotes 5'cap-dependent mRNA translation by preventing the assembly of the eIF4F complex through binding of the eIF4E (Saxton & Sabatini, 2017).

In case of the lipid/nucleotide and glucose metabolism, the mTORc1 controls different transcription factors. Two interesting targets in this context are the Hypoxia-inducible factor 1 α (HIF1 α) and the sterol responsive element binding protein (SREBP) (Saxton & Sabatini, 2017). While the SREBP controls the expression of genes involved in fatty acid and cholesterol biosynthesis (Porstmann et al., 2008), the HIF1 α promotes the expression of a variation of glycolic enzymes (Düvel et al., 2010). Both transcription factors are directly activated by mTORc1 through phosphorylation or indirect through interaction of mTORc1 with target related inhibitors (Düvel et al., 2010; Peterson et al., 2011).

In addition to controlling these anabolic processes, mTORc1 also influences a variation of catabolic systems. One catabolic process that is suppressed by mTORc1 to promote cell survival and growth is the autophagy. The mTORc1 controls this process through the interaction with key activators like the 5' AMP-activated protein kinase or through impairment of transcription factors like TFEB (J. Kim et al., 2011; Martina et al., 2012).

1.2.2 Downstream of mTORc2

Although the role of mTORc2 is not well understood, one of the main functions of mTORc2 is to control the organization of the cytoskeleton (Saxton & Sabatini, 2017). This duty is mediated by the interaction of complex 2 with several members of the Protein kinase C family (Saxton & Sabatini, 2017). For example, mTORc2 controls PKC α and PKC γ (Saxton & Sabatini, 2017). These two proteins have been described to contribute to remodelling of the actin cytoskeleton and cell migration in different fibroblasts as well as brain and Purkinje cells (Jacinto et al., 2004; Thomanetz et al., 2013).

Besides its role in the organization of the cytoskeleton, mTORc2 is also described in the context of the PI3K/AKT pathway (D. D. Sarbassov et al., 2005). This pathway is one of the most important intracellular systems in cells, contributing to a variety of cell survival related biological processes like proliferation, growth and metabolism (D. D. Sarbassov et al., 2005). The mTORc2 phosphorylates and activates the Protein kinase B (AKT), a key component of this pathway (D. D. Sarbassov et al., 2005). Although mTORc2 seems to be one of the main control points of AKT, it should be mentioned that mTORc2-dependent phosphorylation does not seem to be required for all AKT related interactions (D. D. Sarbassov et al., 2005). For example, it has been shown that the phosphorylation of TSC2 through AKT seems to be independent of the protein complex (Guertin et al., 2006; Jacinto et al., 2006).

1.2.3 mTOR and cancer

The mTOR signaling pathway is one of the most frequently mutated pathways in a wide variety of tumour entities. Especially the upregulation of the mTOR pathway activity has been connected to high tumour growth and progression in different studies (Hua et al., 2019; Saxton & Sabatini, 2017). In panNET, immunohistochemical examinations revealed a high percentage of tumours with upregulated mTOR pathway activity, whereby the exact numbers differ between 33

% in a study from Lamberti et al. and 26 to 52 % in a study from Komori et al. (Komori et al., 2014; G. Lamberti et al., 2017). In both studies, the dysregulation of mTOR was correlated with high invasion, high proliferation and an advanced-stage of panNET (Komori et al., 2014; G. Lamberti et al., 2017).

In general, overexpression of mTOR in cancer can be associated with three different biological reasons: mutations in the *mTOR* gene itself, mutations in different components of mTOR and mutations of upstream targets of mTOR. Mutations in the *mTOR* gene itself are rarely found in human cancer types but studies showed that these mutations are correlated with the activation of the mTOR signaling pathway in colorectal cancer cells and mice fibroblasts (Edinger & Thompson, 2004; Sekulić et al., 2000). Moreover, a comparison of different tumour genome sequencing data revealed 33 mutations in the C-terminal region of mTOR that have the potential to induce pathway hyperactivation (Grabiner et al., 2014). Grabiner *et al.* showed that these mutations appear in a wide variety of cancer types and they suggest that the activation of the mTOR complex may be attributed to an inhibited interaction between mTOR and its regulatory subunit DEPTOR (Grabiner et al., 2014).

Besides mutations in the *mTOR* gene itself, genetic aberrations in different components of the two mTOR complexes have also been associated with elevated mTOR pathway activity (Conciatori et al., 2018). Especially the subunit RICTOR of mTORc2 seems to be linked to pathway hyperactivation (Conciatori et al., 2018). Enrichment of RICTOR has been observed in non-small-cell lung cancer and breast cancer (Cheng et al., 2015; Morrison Joly et al., 2016; Pilotto et al., 2017).

The most frequently reason for hyperactivation of the mTOR pathway is the occurrence of mutations in various upstream targets of mTOR. These mutations manifest as loss-of-function mutations in tumour suppressor genes and gain-of-function mutations in oncogenes (Conciatori et al., 2018; Tian et al., 2019). For example, mutations in the tumour suppressor PTEN, KRAS and BRAF are associated with upregulated mTOR pathway activity and could be observed in breast cancer, kidney cancer and NETs (Conciatori et al., 2018; DeGraffenried et al., 2004; Scarpa et al., 2017; Zoncu et al., 2011). In panNET, a whole-genome sequencing analysis also identified PTEN as one of the most frequently mutated genes taken together with MEN1, DAXX and ATRX (Jiao et al., 2011; Scarpa et al., 2017). This observation is supplemented by the finding that the mTOR signaling pathway is one

of the top three upregulated pathways in 102 primary panNETs, right after chromatin remodelling and DNA damage repair (Scarpa et al., 2017).

1.2.4 Inhibitors of the mTOR signaling pathway

Inhibitors of the mTOR signaling pathway are a central element in the targeted drug therapy of well or moderately differentiated and metastatic panNET. In general, there are three different groups of inhibitors that are already used for treatment of patients or are in clinical trial.

Figure 3: Inhibition of the mTOR signaling pathway.

There are three categories of inhibitors of the mTOR signaling pathway. Firstly, the rapalogs that consists of derivate of rapamycin and mainly inhibit the activity of the mTORc1 through impairment of the mTOR-Raptor relationship. Secondly, ATP competitive inhibitors that perform allosteric interaction with the ATP-binding pocket and therefore inhibit mTORc1 and mTORc2. Thirdly, dual PI3K/mTOR inhibitors that inhibit both mTOR complexes as well as PI3K, due to the sequence homology of PI3K and mTOR. (Malley & Pidgeon, 2016)

The first group of mTOR inhibitors consists of rapalogs, which are water-soluble derivates of rapamycin with a good pharmacokinetic (Hua et al., 2019). They inhibit the mTOR pathway by impairing the relationship between mTOR and its subunit Raptor through interaction with the 12 kDa FK506-binding protein (FKBP12) (J. Chen

et al., 1995; Chiarini et al., 2019). Interestingly, these substances do not induce apoptosis or other cell death related mechanisms, they only lead to cell growth arrest (Hua et al., 2019). As Raptor is a subunit of mTORc1, this inhibition leads to downregulation of the mTORc1 activity without affecting mTORc2. The best-known rapalogs are everolimus (trade name: Afinitor®) and temsirolimus (trade name: Torisel®), which were initially used to treat renal cell carcinoma but were later approved for the treatment of advanced breast cancer and panNET (Figure 3, Hua et al., 2019; Roskoski, 2022). Although the efficiency of rapalogs has been clinically proven in different tumour entities, there are no established biomarkers for the response of patients to these substances. There has been a study that postulate KRAS as a prognostic marker for resistance of patients to rapalog induced mTOR inhibition (Yeung et al., 2017).

The second group of mTOR inhibitors consists of ATP competitive inhibitors. These substances inhibit both mTOR complexes, as they directly target the ATP-binding pocket of mTORc1 and mTORc2 through allosteric interaction (Amin et al., 2021; Neil et al., 2016). In comparison to rapalogs, ATP competitive inhibitors not only lead to cell growth arrest, they also induce apoptosis. Two known ATP competitive mTOR inhibitors are MLN018 (Sapanisertib) and AZD2014 (Vistusertib), which are being investigated for use in various tumour entities such as leukaemia, breast cancer and colorectal cancer (Figure 3, Gökmen-Polar et al., 2012; Guichard et al., 2015; Rashid et al., 2018).

The third and last group consists of dual PI3K/mTOR inhibitors. These inhibitors are based on the observation that the lipid kinase PI3K has high sequence homology with mTOR in its hinge-region (Feldman & Shokat, 2010; Panwar et al., 2023; Schenone et al., 2011). Therefore, these inhibitors not only inhibit both mTOR complexes, they also impair the activity of PI3K (Feldman & Shokat, 2010; Schenone et al., 2011). Representatives of this group include NVP-BEZ235 (Dactolisib) and GDC-0980 (Apatolisib) that are still in clinical trial (Figure 3, Dolly et al., 2016; Shi et al., 2018).

In addition to these specific inhibitors of the mTOR signaling pathway, multikinase inhibitors such as sunitinib (trade name: Sutent®) are also used in the treatment of panNET. Especially kinases that influence tumour growth, angiogenesis and metastasis are of interest in this context (Chow & Eckhardt, 2007). Furthermore, there has been recent discussion regarding the potential benefits of combined

treatment of mTOR inhibitors with inhibitors targeting cellular metabolism for patients (Tsolli et al., 2018).

1.3 Mitochondria and cancer

The development and formation of malignant tumours as a consequence of neoplastic disease is very complex. For a better understanding of this process, the most important characteristics of tumour formation have been summarized under the term “hallmarks of cancer” (Figure 4), including resistance of cell death, activation of invasion/metastasis and deregulation of cellular energetics (Hanahan, 2022).

Figure 4: The hallmarks of cancer.

The capabilities of neoplastic disease to form malignant tumours can be summarized in ten different categories. (modified according to Hanahan, 2022)

Especially deregulation of cellular energetics has been described for a long time, as Warburg *et al.* discovered the so-called Warburg effect in 1924 (Warburg, 1924). This effect is based on the observation that tumours produce high amounts of lactate in the presence of oxygen by a process called “aerobic glycolysis”, while normal cells produce energy by the mitochondria related oxidative phosphorylation (Liberti & Locasale, 2016; Wallace, 2012; Warburg, 1924). Although the aerobic glycolysis is energy inefficient in comparison to the oxidative phosphorylation, it can be beneficial for cancer cell development through the increased glycolytic flux that supports cell proliferation by providing biosynthetic precursors (Liberti & Locasale, 2016). However, new research has shown that not all tumours shift to glycolysis for energy production. In fact, there is a huge heterogeneity in cellular energetics in different

tumours or tumour classes, where in most of them glycolysis does not occur instead of mitochondrial respiration (Koppenol et al., 2011). Although Warburg's observation was made a long time ago, it forms the basis for the observation that metabolic signaling pathways and glycolysis may represent a promising approach to the treatment of cancer.

In general, mitochondria are the main energy source in most eukaryotic cells as these organelles harbor the oxidative phosphorylation system (OXPHOS) that generates the energy currency ATP. Moreover, they also play an important role in many other biological processes like calcium signaling, apoptosis or cellular senescence (Habbane et al., 2021; Osellame et al., 2012). Mitochondria are unique organelles as they contain their own 16,569 bp long DNA, known as the mitochondrial DNA (mtDNA) or mitogenome (Habbane et al., 2021). This genome encodes 37 genes, including 22 transfer RNAs and 2 ribosomal RNAs that are essential for mitochondrial respiration and ATP production (Habbane et al., 2021). In recent years, a wide variety of somatic mutations have been described in these genes in different tumour entities and have been connected to dysregulation of the OXPHOS (Schon et al., 2012; Stewart et al., 2015). It has been reported that these mutations may stimulate the neoplastic formation of tumours and facilitate the adaptation to changing bioenergetics (Brandon et al., 2006; Wallace, 2012). Although the role of mtDNA mutations in pancreatic cancer is not well understood, it has been reported that mutations in different genes of the mtDNA occur in a variety of pancreatic cancer cell lines and that these changes may be beneficial for formation and invasion of pancreatic tumours (Jones et al., 2001; Moro, 2021).

Besides the OXPHOS related genes, the mtDNA harbours two non-coding regions that are called control region and displacement loop (Habbane et al., 2021). These secondary structures of the DNA are important for the replication and transcription of the genome as they temporarily contain a short complementary DNA strand that leads to separation of the double-stranded DNA molecule (Nicholls & Minczuk, 2014). Additionally to these regions, the replication and transcription of the mtDNA depends on nuclear encoded proteins like the Peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1 α) or the mitochondrial transcription factor A (TFAM) (Habbane et al., 2021).

1.3.1 mTOR and mitochondria

Given the central role of mTOR in different biological processes, it is not surprising that there is some evidence that the protein impacts the mitochondrial biogenesis. Genome-wide polysome profiling of translational targets of rapalogs revealed, that the inhibition of mTOR impacts a wide variety of mRNAs related to nucleus encoded mitochondrial proteins (Larsson et al., 2012). In total, 14 % of all identified mRNAs were associated with mitochondrial functions (Larsson et al., 2012). These mRNAs included mRNAs encoding for components of the oxidative phosphorylation (mainly complex V (ATP synthase)) and proteins that are involved in the transcription and translation of the mtDNA (for example TFAM) (Larsson et al., 2012; Morita et al., 2013). In addition to these observations, Morita *et al.* showed that inhibition of mTOR leads to reduced mitochondrial mass, mtDNA content and up to 35 % reduced mitochondrial respiration in breast cancer cells, underlying the impact of mTORc1 on a variety of mitochondrial parameters (Morita et al., 2013). The study attributes the effect of mTORC1 on mitochondria to its interaction with 4EBP, which influences the eIF4F initiation complex (Morita et al., 2013).

Another process regulated by mTORC1 are mitochondrial dynamics, which includes the processes of mitochondrial fusion and fission (Trotta & Chipuk, 2017). Fusion refers to the merging of two mitochondria into a single organelle, while fission describes the process by which one mitochondrion divides into two separate mitochondria (Trotta & Chipuk, 2017). In general, mitochondrial dynamics are important for the information exchange between organelles during stress situations, mtDNA replication and cell division (Trotta & Chipuk, 2017). A key regulator of mitochondrial fission is the mitochondrial fission process protein 1 (MTFP1), which is located at the inner mitochondrial membrane (Tondera et al., 2005). The translation of this protein has been shown to be impacted by mTORc1 via 4E-BP and that inhibition of mTORC1 suppresses this process, leading to mitochondrial elongation (Morita et al., 2017). Notably, mTOR inhibitors like rapamycin slow down cell growth by regulating metabolism and protein synthesis, which has cytostatic effects on cells. When mitochondrial fission is additionally enhanced, the mitochondrial structure is altered to such an extent that it triggers stress and activates apoptosis (Morita et al., 2017). As a result, the combination of mTOR inhibition and increased fission becomes cytotoxic (Morita et al., 2017).

1.4 Aim of the work

Neuroendocrine tumours are a rare malignancy that is difficult to medicate as the treatment options mainly include classical cancer treatments such as chemotherapy or surgery. Therefore, the discovery of targeted drug therapy was a great breaking point for the treatment of NETs. They offered the opportunity to specifically target cell growth or cell proliferation related proteins with less side effects for the patient in comparison to common chemotherapy drugs. In NETs one of the main targets for this form of therapy is the mTOR signalling pathway, which is based on the observation that this pathway is highly activated in a great number of NETs. As it has also been shown that mTOR impacts mitochondrial function and the expression of nuclear-encoded mitochondria-related genes, there have been recent discussions regarding the potential benefits of combined treatment with inhibitors targeting cellular metabolism in patients. However, there remains limited understanding of the interplay between mTOR and mitochondria, particularly within NETs. Therefore, the objective of this study was to identify proteins that connect these two systems, with a primary focus on panNETs due to the heterogeneity of NETs.

For this propose, a cohort of 157 panNET was established and the activity of the mTOR signalling pathway determined by expression analysis of the phosphorylated ribosomal protein S6 in a tissue micro array (TMA). In the next step, RNA sequencing was performed on 69 panNET samples from the initial cohort, both with and without mTOR pathway activity, to identify targets associated with both mTOR and mitochondrial function. The expression of the identified genes that was subsequently examined using quantitative PCR. Functional consequences of the observed molecular alterations were assessed in cellular assays using BON1 and QGPT1 cells.

2. Material and methods

2.1 Material

2.1.1 Chemical

Chemical	Manufacturer
Acrylamid Mix, Rotiphorese®Gel 30 (37, 5:1)	Carl Roth, Karlsruhe, Germany
Deoxyribonucleotide triphosphate (dNTP) mix	Thermo Fisher, Waltham, USA
Dimethyl sulfoxide (DMSO)	Thermo Fisher, Waltham, USA
Dulbecco's Phosphate Buffered Saline (PBS)	Sigma-Aldrich, St. Louis, USA
Fetal calf serum (FCS)	Sigma-Aldrich, St. Louis, USA
Gel Loading Dye, Purple (6X)	New England, Frankfurt aM, Germany
Isopropanol	Merck, Darmstadt, Germany
L-Glutamin, 200 Mm Stock	Thermo Fisher, Waltham, USA
Lysis buffer (10x)	Cell Signaling, Frankfurt aM, Germany
M-MLV Reverse Transcriptase	Promega, Walldorf, Germany
Penicillin-Streptomycin	Sigma-Aldrich, St. Louis, USA
Protease/Phosphatase Inhibitor Cocktail (100X)	Thermo Fisher, Waltham, USA
Protein Assay Reagent	Bio-Rad, California, USA
Proteinase K from Tritirachium album	Sigma-Aldrich, St. Louis, USA
Pyruvat	Sigma-Aldrich, St. Louis, USA
Random Primers	Promega, Walldorf, Germany
Bovine serum albumin (BSA)	Roth, Karlsruhe, Germany
RNasin®Plus Rnase Inhibitor	Promega, Walldorf, Germany
RPMI 1640 Medium, GlutaMAX™ Supplement	Thermo Fisher, Waltham, USA
Sodium dodecyl sulfate (SDS)	Serva, Heidelberg, Germany
Sodium Hydroxide Solution, 2 M NaOH	Thermo Fisher, Waltham, USA
SYBR™Green PCR Master Mix	Thermo Fisher, Waltham, USA
TRIS-Acetat-EDTA (TAE)-buffer	Thermo Fisher, Waltham, USA
Tris-buffered saline (TBS) 20x powder	ApplieChem GmbH, Darmstadt, Germany
Trizma® base	Merck, Darmstadt, Germany
Trypsin-EDTA	Sigma-Aldrich, St. Louis, USA
UltraPure™ Agarose	Thermo Fisher, Waltham, USA

2.1.2 Buffer and chemical solutions

2.1.2.1 Isolation of the whole cell extract

6x sample buffer	350 mM Tris-HCl; pH 6.8 10,28 % (w/v) SDS 36 % Glycerol 600 mM Dithiothreitol Spatula tip Bromphenol blue ddH ₂ O
Lysis buffer	10 % (v/v) 10x Lysis buffer 2 % (v/v) Protease/Phosphatase Inhibitor ddH ₂ O

2.1.2.2 SDS-Page und Western Blotting

Blocking solution	5 % (w/v) Nonfat dried milk powder in TBS-T
Enhanced chemiluminescence (ECL) detection solution	10 ml Tris-HCl 100 mM; pH 8.5 50 µl Luminol (250 mM in DMSO) 25 µl Coumaric acid (90 mM in DMSO) 4 µl H ₂ O ₂ (30 % (v/v))
PBS (10x)	140 mM NaCl 8 mM Na ₂ HPO ₄ ·7H ₂ O 2 mM NaH ₂ PO ₄ ·7H ₂ O ddH ₂ O
PBS-T	0,1 % (v/v) Tween 20 in PBS (1x)
Ponceau S staining solution	0,5 % (w/v) Ponceau S 1 % (v/v) Concentrated acetic acid
SDS-Page Running buffer (10 x); pH 8.3	250 mM Tris 1.92 M Glycine 1 % (w/v) SDS ddH ₂ O

Stacking buffer, pH 6.8	500 mM Tris-HCl ddH ₂ O
Resolving buffer; pH 8.8	1,5 M Tris-HCl ddH ₂ O
Semi-dry blotting buffer (1 x)	10 % (v/v) Semi-dry blotting buffer (10 x) 20 % (v/v) Methanol ddH ₂ O
Semi-dry blotting buffer (10 x); pH 9-9.2	480 mM Tris 390 mM Glycine 0,375 % (w/v) SDS ddH ₂ O
TBS (10 x); pH 7.6	200 mM Tris 1.38 M NaCl ddH ₂ O
TBS-T	0,1 % (v/v) Tween 20 in TBS (1x)

2.1.3 Oligonukleotides

2.1.3.1 Oligonucleotides used as qPCR-primer.

Qubit® dsDNA-BR-Assay-Kit	Thermo Fisher, Waltham, USA
Qubit® dsDNA-HS-Assay-Kit	Thermo Fisher, Waltham, USA
RNeasy®Plus Mini Kit	Qiagen, Hilden, Germany
WesternBright™ Sirius™ Detection Kit	advansta, San José, USA

2.1.6 Antibody

All primary antibodies were diluted in PBS-T with 5 % BSA. All secondary antibodies were diluted in TBS-T with 5 % nonfat dry milk.

Primary antibodies	Manufacturer	Working solution Western Blotting	Working solution immunohistochemistry
Monoclonal antibody against human Actin (#MAB1501)	Merck, Darmstadt	1:10.000	-
Monoclonal antibody against human Phospho-S6 Ribosomal Protein (pS6) (#4858)	Cell Signaling, Frankfurt aM	1:2.000	1:400
Monoclonal antibody against human S6 Ribosomal Protein (S6) (#2317)	Cell Signaling, Frankfurt aM	1:1.000	1:200
Monoclonal antibody against human PGC1 α (#2178S)	Cell Signaling, Frankfurt aM	1:1.000	-
Monoclonal antibody against human MORTALIN/ Mortalin (#3593)	Cell Signaling, Frankfurt aM	1:1.000	-

Secondary antibody	Manufacturer	Working solution Western Blotting
Rabbit-Antibody (#170-6515)	Bio-Rad, California, USA	1:3.000
Maus-Antikörper (#170-6516)	Bio-Rad, California, USA	1:3.000

2.1.7 Cell lines und cultivation

The adherent human cell lines BON1 and QGP1 which originate from neuroendocrine tumours located in the pancreas were used for all cell biological assays.

Standard growth medium for adherent panNET cell lines

The used panNET cell lines were cultured in RPMI 1640 Medium, GlutaMAX™ Supplement Medium with 10 % FBS, 1 % Penicillin-Streptomycin and 10 % L-Glutamin.

Freezing medium for adherent panNET cell lines

For cryopreservation, the adherent panNET cell lines were stored in freezing medium containing 10 % DMSO and 90 % FBS.

2.2.1 Cohort of panNET for the selection of panNET with activated mTOR pathway signaling

To identify panNET with activated mTOR pathway, a well-characterized cohort of 157 panNETs was established. The tumour stage of patients was classified based on the ENETS/ UICC and the grading of the tumours was classified based on the WHO (Klöppel et al., 2010; Rindi et al., 2022). Detailed patient characteristics are displayed in Table 4. The local ethics committee (Ethics Committee of the Rhineland-Palatinate State Medical Association, Mainz, Germany) approved the study design, and all samples were handled in compliance with the standards proposed by the Declaration of Helsinki

Table 4: Summary of clinic pathological features in the study population (n = 157).

2.2.1.2 Cohort of panNET for the identification of molecular alterations

For the following molecular analyses, the number of panNET cases had to be adjusted due to low RNA quality and quantity. Therefore, all assays except the immunohistochemical staining were performed using 69 of the initially 157 panNET cases. All clinical pathological features of this population are listed in Table 5.

Table 5: Summary of clinic pathological features in the experimental population (n = 69).

2.2.2 Immunohistochemistry

2.2.2.1 Tissue microarray (TMA)

To analyse the molecular interaction between mTOR signaling and mitochondria in neuroendocrine tissue, the mTOR activity had to be determined for the established cohort of panNET. Since phosphorylated S6 has been demonstrated to be a good indicator for the activity of mTOR signalling in cancer cells and mice tissue (Knoll et

al., 2016; Stelzer et al., 2010), the expression of the protein was analyzed in a TMA comprising all 157 paraffin blocks of the cohort. Therefore, hematoxylin and eosin stained tissue sections were cut from these blocks and the tumour area was marked by a pathologist. Two tissue cores per patient within the marked area were then removed and assembled on a new paraffin block in an array pattern. In total, 80 tissue cores with 1.5 mm in diameter could be collected on one paraffin block and two samples from muscle tissue were included as quality control. The new paraffin block was cut using a microtome, resulting in sections that were transferred to a microscope slide and immunohistochemically stained. The phosphorylated form of S6 was stained as an indicator for mTOR activity and the un-phosphorylated form of the protein was stained as a control. All used antibodies and working solutions are listed in 2.1.6. The TMA was accomplished in cooperation with the BioBank of the university medical center Mainz. Analysis of the immunohistochemical staining was performed using Qupath (Bankhead et al., 2017) and the expertise of a pathologist.

2.2.3 Nucleic acid extraction from FFPE tissue

2.2.3.1 Preparing of tissue sections

Isolation of genomic DNA and RNA from FFPE tissue samples was performed using unstained FFPE tissue sections. These sections were freshly prepared by cutting paraffin blocks. Therefore, these blocks were placed on a cooling plate (-14 °C) for at least 10 minutes and were cut into 8 µm thick sections using a rotary microtome (Microm HM355S, ThermoFisherScientific). These tissue sections were placed into a 37 °C water bath and transferred to a microscope slide. The generated slides were then placed on a heating table (41 °C) for at least 10 minutes. After this drying process, the FFPE tissue sections could be used for DNA and RNA extraction.

2.2.3.2 DNA extraction

For targeted isolation of DNA from the tumour tissue of panNET, the tumour area had to be identified and marked on the freshly prepared FFPE tissue sections. Hematoxylin and eosin stained tissue sections were used as a template for each sample and the tumour area was marked on these sections by a pathologist. This selection was then transferred on the unstained microscope slides and DNA was isolated according to the manufacturer's protocol with the Maxwell® RSC DNA FFPE Kit from Promega. Therefore, the tumour area of the section was scraped off the

slide with a scalpel and added to a new tube with sample buffer. The isolation of the nucleic acid from the material was carried out through a Proteinase K digestion, which was prepared according to the manufacturer's instructions and incubated overnight at 70 °C. At the beginning of the incubation, the samples were shaken at 500 rpm for 2 to 3 hours for better disruption of the cells. The next day, isolation of the DNA was performed using the Maxwell®RSC from Promega according to the manufacturer's protocol. The isolation is based on paramagnetic particles (beads) that bind nucleic acids and different washing steps for obtaining the optimal purity of DNA (Figure 5). Concentration of the DNA was measured using the Qubit™ Fluorometer (2.2.3.4 Measurement of nucleic acid concentration).

Figure 5: Schematic description of the automated process of DNA/RNA isolation with the Maxwell instrument.

The sample material is added into the cartridge (1) and mixed and lysed by using a plunger (2). The released nucleic acids are bound by beads (3-4) and purified through different washing steps (5-6). (modified according to Promega)

2.2.3.3 RNA extraction

Isolation of the RNA was performed from the same tumour area as isolation from DNA according to the manufacturer's protocol with the Maxwell® RSC RNA FFPE Kit from Promega. Similar to DNA isolation, the tumour area was scraped off with a scalpel but the resulting sample material was transferred into a new tube with

mineral oil for deparafinization. This step was followed by incubation at 80 °C for two minutes and lysis of the material through Proteinase K digestion. All steps were prepared according to the manufacturer's instructions. The loading of the cartridge and the measurement of the concentration of the RNA were performed equivalent to the DNA isolation (see 2.2.3.2).

2.2.3.4 Measurement of nucleic acid concentration

Table 6: Approach for the concentration measurement of nucleic acids with the Qubit® dsDNA HS or BR Assay Kit.

	Standard 1 or 2 [µl]	Sample [µl]
Measurement solution*	190	199
DNA/ RNA	10	1

*Measurement solution = DNA/RNA reagent + buffer (1:200)

Measurement of the concentration of nucleic acids was performed using the Qubit™ 1.0 Fluorometer. For DNA, the Qubit® dsDNA HS Assay Kit (0,2 – 100 ng/µl) or the Qubit® dsDNA BR Assay Kit (2-1.000 ng/µl) from ThermoFisher were used, depending on the expected concentration range. The Qubit™ RNA HS Assay Kit was used for RNA concentration measurement. The samples were prepared according to Table 6. The calculation of the final concentration of the DNA or RNA was performed by the fluorometer using the following formula:

$$\text{Concentration of the sample} = \text{QF value} * 200/x$$

$$\text{QF value} = \text{fluorescence value of the Qubit® Fluorometer}$$

$$x = \text{used } \mu\text{l of the sample}$$

2.2.4 Next generation sequencing (NGS)

The next generation sequencing is a high-throughput technique for identification of different genomic variations of the DNA in short time. In this work, NGS-analysis was performed according to the bridge amplification form illumina. This system is based

on the following four steps: preparation of the DNA-library, cluster amplification, sequencing and analysis of data.

Figure 6: Schematic description of the bridge amplification by Illumina.

The bridge amplification by Illumina is based on the following four steps: (A) preparation of the DNA-library, (B) cluster amplification, (C) sequencing and (D) bioinformatic data analysis. (Illumina, Inc., 2017)

In the first step of NGS-Analysis, a DNA library is generated by fragmentation of the DNA and ligation of adapters on these fragments (Figure 6). The adapters include primer binding sides and so-called unique molecular identifiers sequences (UMIS). These UMIS allow differentiation between artifacts and actual mutations by labelling each DNA library sample. For cluster amplification, the DNA libraries are loaded into a flow cell equipped with complementary adapter oligonucleotides (Figure 6).

Amplification is carried out through the mentioned bridge amplification as described before (Goodwin et al., 2016), resulting in thousands of DNA clusters each originating from a single library fragment. The actual sequencing step is carried out by the sequencing by synthesis (SBS) technology by Illumina. This method requires fluorescence labelled nucleotides that are applied into the nucleic acid chain during each sequencing cycle (Figure 6). The resulting fluorescence signal is detected and documented for each DNA cluster on the flow cell and followed by data analysis (Figure 6).

2.2.4.1 Molecular characterization of the mitochondrial genome of panNET

To analyze the possible impact of the mTOR activity status on the frequency of somatic mutations in the mitochondrial genome, 69 panNET samples from the established cohort were selected for NGS-analysis. The selected samples included 21 panNET with upregulated activity of the mTOR signaling pathway and 48 cases without upregulation of the pathway. The classification of the panNET is based on the results of the immunohistochemistry in 2.2.2. For identification of tumour specific mutations, NGS-analysis was carried out for tumour and normal tissue of each patient. Preparation of DNA libraries was performed using the QIAseq Targeted DNA Human Mitochondria Panel (DHS-105Z, Qiagen), with an average input of 100 ng FFPE-DNA per sample. The DNA libraries were quantified as described in 2.2.3.4 and diluted to a concentration of 4 nM. In the next step, libraries were further diluted by adding 0.2 nM NaOH to a final concentration of 10 pM and pooled, to ensure a sequencing depth of 1 million reads per sample. Sequencing of the mitochondrial genome was performed using the Illumina MiSeq System and paired-end sequencing with 2 x 151 bp reads. For data analysis, the MiSeqReporter Software from Illumina and CLC Workbench from Qiagen were used in combination with an in-house analysis pipeline. This pipeline aligns the generated reads with the Cambridge Reference Sequence (rCRS) of the human mitochondrial DNA (NC_012920) and the detected somatic mutations with the MITOMAP database (Kogelnik et al., 1996).

2.5 RNA-sequencing

To identify differentially expressed genes that are affected by the mTOR activity in panNET, a gene expression profile of 69 panNET cases was created. These included 21 panNET with activated mTOR pathway and 48 panNET without upregulated mTOR activity. RNA sequencing enables the identification of expression

differences in the entirety of all genes in the tissue, whereby in the following we have mainly focused on mitochondria-associated genes and target genes of the mTOR signaling pathway.

2.2.5.1 cDNA synthesis and quantification for RNA-Sequencing

In the first step of the RNA-sequencing, the cDNA synthesis was performed using the ProtoScript® II First Strand cDNA Synthesis Kit (New England Biolabs) according to the manufacturer’s instructions. An input of 750 ng RNA per sample was used and the approach for the random primer mix was selected. In deviation from the manufacturer’s instructions, only 0.5 µl of the random primer mix were used in the PCR for denaturation of the samples. The concentration of the cDNA was measured according to 2.2.3.4.

2.2.5.2 Library preparation and sequencing

Library preparation was performed using the AmpliSeq™ Transcriptome Human Gene Expression Panel (Illumina, San Diego, CA, USA) and the AmpliSeq™ Library PLUS Kit (Illumina, San Diego, CA, USA) according to the manufacturer’s instructions. The amount of cDNA used for amplification of the targets was calculated according to the following formula:

$$\frac{\text{Sample input for library preparation}}{\text{Concentration cDNA} \times (1/\text{Dilution factor cDNA})} = \text{Amount of cDNA for amplification (Max. 8 } \mu\text{l)}$$

Deviating from the protocol, the following PCRs for amplification of the targets and amplification of the libraries were performed.

Table 7: Settings for PCR for amplification of targets and amplification of libraries.

The deviations from the manufacturer's protocol are marked in red

Amplify targets	Amplify library
99 °C for 15 seconds	98 °C for 2 minutes
99 °C for 15 seconds	98 °C for 15 seconds
60 °C for 16 minutes	64 °C for 1 minute
} 13 cycles	} 9 cycles

The quantity and quality of the final libraries was measured using the 2100 Bioanalyzer (Agilent, Santa Clara, CA, USA). Based on this measurement the libraries were diluted to the final loading concentration according to the “Denature

and Dilute Libraries Guide” for the NextSeq500 and 550 (Illumina, San Diego, CA, USA). Library sequencing was performed using the NextSeq500 system (Illumina, San Diego, CA, USA) with single-read sequencing and 76 bp reads. The sequencing depth was 20 million reads per sample.

2.2.5.3 Bioinformatic analysis of data

The generated raw data from the RNA-sequencing were quantified in cooperation with Dr. Michael Kloth of the Institute of Pathology (Mainz). This step included removal of adapter sequences and low-quality reads and was performed using the Salmon tool (Patro et al., 2017).

The following differential expression analysis was carried out with the Bioconductor-DESeq2 package for R (version 4.3.0, R Core Team, 2021) according to the DESeq2 manual (version 1.42.0, Love et al., 2014). As a pre-filter option only samples with a transcript count over 5 were included into analysis. Genes with Benjamin Hochberg adjusted p-value (padj) ≤ 0.05 were considered significant. The detailed code is described in the supplementary Figure S 1. Stable identifiers (Ensembl ID's) matching these genes were extracted using the g:Profiler online tool (Kolberg et al., 2023, <https://biit.cs.ut.ee/gprofiler/gost> (last update: 16.01.25)).

In the next step, Gene Set Enrichment Analysis (GSEA) was performed on the wald-statistic value of all samples using the GSEA software provided by Broad Institutes (Mootha et al., 2003; Subramanian et al., 2005 <http://www.broad.mit.edu/gsea/> (last update: 08.07.24)). GSEA was run on 1000 permutation mode on gene-set label to generate False Discovery Rate (FDR) and enrichment score (ES) for each gene set. Significant gene sets were filtered based on FDR q-values (cutoff: 0.05). The detailed settings for GSEA are described in the supplementary Figure S 2.

2.6 Gene expression analysis using qPCR

2.6.1 cDNA synthesis and quantification for qPCR-Analysis

For gene expression analysis, 700 to 900 ng of total RNA isolated from tissue slices (2.2.3.3) or from cultivated cells (2.2.8.4) were reverse transcribed into cDNA using the M-MLV Reverse Transcriptase. Therefore, RNA was denatured by adding 11 μ l of RNA (700 to 900 ng) and 3 μ l Random-Primer together. This mixture was then incubated for 5 minutes at 70 °C and immediately transferred on ice for prevention of renaturation of the RNA. In the next step, 5 μ l 5x buffer (Promega, Walldorf,

Germany); 0.8 μ l RNAsin-PLUS (Promega, Walldorf, Germany), 1 μ l M-MLV Reverse Transcriptase (Promega, Walldorf, Germany) and 4.2 μ l of 2.5 mM dNTPs (Invitrogen™ by Thermo Fisher Scientific Waltham, MA, USA) were added to the RNA-Primer-Mix on ice and incubated for 60 minutes at 40 °C.

2.6.2 Primer design

If not stated otherwise, the oligonucleotide primers used in this study were generated using the program Primer3Plus (Untergasser et al., 2012, <https://www.primer3plus.com/index.html> (last update: 16.01.25)) or Primer-BLAST provided by the National Library of Medicine (Ye et al., 2012, <https://www.ncbi.nlm.nih.gov/> (last update: 17.07.24)). The reference sequences for selection of primers in the targeted regions also originated from the National Library of Medicine (<https://www.ncbi.nlm.nih.gov/> (last update: 17.07.24)). Primer length was set at 20 bp and the product size ranged between 100 and 150 bp. Melting temperature was set between 58 and 62 °C with an optimal temperature at 60 °C. The percentage of guanine-cytosine content in each primer was set between 50-55 %. All used primers and their origin are listed in 2.1.3. All used primer pairs were diluted to a final concentration of 10 μ M with water before use.

2.6.3 qPCR-analysis

The qPCR-analysis of cDNA isolated from the FFPE tissue slices was performed in triplicates for 21 panNET with activated mTOR signaling pathway and 48 panNET with no activation of mTOR. The samples were prepared as followed:

Table 8: The qPCR reaction mix used for gene expression analysis.

	Volume per reaction [μ l]
SYBR™ Green PCR Master Mix 5	5
forward primer [10 μ M]	0.2
reverse primer [10 μ M]	0.2
HPLC-water	3.6
cDNA template (3-5 ng/ μ l)	1
total volume	10

To measure PCR efficiency, a 1 to 4 dilution series was assayed for every primer starting with a concentration of 3 to 5 ng/μl and ending at 0.04 to 0.07 ng/μl. This dilution series was carried out using a standard consisting of a pool of 10 panNET without mTOR signaling pathway activity. Moreover, a reaction mix with HPLC-water instead of cDNA was assayed as a control against contamination. The following parameters were used for thermal cycling:

Table 9: PCR set up for qPCR.

Temperature	Incubation time	Stage
50 °C	2 minutes	Hold Stage
95 °C	10 minutes	
95 °C	15 seconds	PCR Stage (40 cycles)
60 °C (data acquisition)	1 minute	
95 °C	15 seconds	Melt Curve Stage
60 °C	1 minute	
95 °C (data acquisition)	15 seconds	

The qPCR-analysis of cDNA isolated from cultivated cells was performed in a similar way, with a different standard for measuring the PCR efficiency. Instead of a pool of samples, the untreated control of the panNET cells was used as the starting point of the dilution series. Data analysis of all qPCR results was performed using the “ $2^{-\Delta\Delta Ct}$ Method” as described previously (Livak & Schmittgen, 2001).

2.2.7 Cell culture assays

All cell culture assays were performed under sterile conditions using a laminar flow cabinet. The used chemicals and media were stored at 4 °C and warmed to 37 °C before use. All cells were considered mycoplasma free before use.

2.2.7.1 Cell culture of human pancreatic neuroendocrine cells

The human pancreatic neuroendocrine cell lines BON1 and QGP1 were considered mycoplasma free before use and authenticated by the Multiplexion GmbH (Heidelberg, Germany; Schmitt & Pawlita, 2009).

According to the growth characteristics and health status, cells were passaged twice a week (average confluency 70 - 80 %) in a ratio of 1:2 to 1:4. Therefore, cells were

washed with PBS (w/o Mg^{2+}/Ca^{2+}) and detached using Trypsin/EDTA-solution for 5 minutes at 37 °C. Cells were then transferred to standard growth medium (see 2.1.7) in a T75 flask and incubated at 37 °C and 5 % CO_2 .

For long-term conservation, the cells were stored at -80 °C in freezing medium (see 2.1.7). Therefore, the cells were detached and transferred to growth medium as described before. The cells were then centrifuged at 1,000 rpm for 5 minutes at 4 °C. The medium was aspirated, and the resulting cell pellet was resuspended in 1 ml freezing medium and transferred to a cryo vial. For a gentle freezing process, the vial was placed in a freezing box that guarantees freezing of cells at a rate of -1 °C per minute.

2.2.8 Biochemical and molecular biology methods

The preparation of whole cell lysates and the isolation of DNA as well as RNA were carried out after cultivation of the cells at culture dishes with a diameter of 6 cm. For determination of the necessary cell number, cells were counted using a Neubauer chamber (M. Zhang et al., 2020). If not stated otherwise, 1 million cells were seeded per culture dish.

2.2.8.1 Modulation of gene expression

2.2.8.1.1 Transient transfection of siRNA oligonucleotides and modulation of the mTOR pathway activity

For the transient knockdown of different genes, panNET cancer cells were transfected with small interfering RNA (siRNA) oligonucleotides using Lipofectamine®2000 (Invitrogen, Carlsbad, CA, USA). Information's for all used siRNAs are listed in 2.1.3.2. One hour before transfection, growth medium was replaced with Opti-MEM (Invitrogen, Carlsbad, CA, USA) and two solutions were prepared for transfection and incubated separately for 5 minutes at room temperature. One solution contained 5 nM siRNA diluted in 100 μ l Opti-MEM and the other solution contained Lipofectamin 2000 (ratio 1:2, DNA:Lipofectamin) diluted in 100 μ l Opti-MEM. After the incubation, both solutions were mixed and incubated for 20 minutes at room temperature. In the next step, the transfection mix was added to the cells and incubated at 37 °C and 5 % CO_2 . After 5 to 6 hours the Opti-MEM medium was changed to standard growth medium. The cells were incubated for 72 hours before further investigation.

For inhibition of the mTOR signalling pathway, everolimus and temsirolimus were used in a concentration of 1 μ M for 72 h.

2.2.8.2 Preparation of whole cell lysate

All following steps were performed on ice. For preparation of whole cell lysates, cells grew to a confluency of 70 to 80 %. The cells were washed with ice-cold PBS and scraped off the culture dish surface with 50 to 70 μ l lysis buffer, containing 10x cell lysis buffer (Cell Signaling Technology, Frankfurt aM, Deutschland), 2% Protease/Phosphatase Inhibitor (Cell Signaling Technology, Frankfurt aM, Deutschland) and water. Cell lysates were incubated for 15 minutes on ice. Afterwards, the lysate was centrifuged at 12,700 rpm for 20 minutes at 4 °C, resulting in a sediment part containing cell compartments and the supernatant containing the desired proteins. The sediment was discarded and the concentrations of the proteins in the supernatant were measured using the Bradford protein assay (Thermo Fisher, Waltham, USA) according to the manufacturer's instructions. The quantity of protein per sample was adjusted to 30 μ g using 6x protein sample buffer and the samples were incubated at 95 °C for 5 minutes for denaturation.

2.2.8.3 SDS polyacrylamide gel electrophoresis and semi-dry western blotting

Proteins which are contained in the whole cell lysate were separated on 10 to 12 % polyacrylamide gels by using SDS polyacrylamide gel electrophoresis (SDS-page).

Table 10: Composition of SDS polyacrylamide gels for electrophoresis.

	Resolving gel		Stacking gel
	10 %	12 %	5 %
ddH ₂ O [ml]	2	1,7	1.15
Rotiphorese® Gel 30 [ml]	1,7	2	0.33
Stacking buffer [ml]	-	-	0.5
Resolving buffer [ml]	1,3	1,3	-
10 % (w/v) SDS [μ l]	50	50	20
10 % (w/v) APS [μ l]	50	50	20
TEMED [μ l]	2	2	2

The concentration of the gels depended on the molecular weight of the protein of interest, whereby proteins with a low molecular weight are resolved in a high percentage gel. The composition of the used stacking and resolving gels is described in Table 10. The SDS-page was performed using a consistent electric voltage of 120 Volt for 90 minutes. In the next step, the separated proteins were transferred to a nitrocellulose membrane (Bio-Rad, Munich, Germany) using a semidry blotting system. The composition of the semidry blot is described in Figure 7. The proteins were transferred with the Trans-Blot® Turbo™ Blotting System from BioRad using an electric voltage and amperage of 25 Volt and 300 mA for 30 minutes.

Figure 7: Composition of a semidry blot. (modified according to Gravel, 2009)

2.2.8.4 Immunoblot analysis

The nitrocellulose membrane was incubated and reversibly stained with Ponceau S staining solution. This screening was carried out to guarantee the successful transfer of proteins and to cut the membrane according to the following antibody treatment. Blocking was performed for 1 hour at room temperature with blocking solution to prevent unspecific binding of antibodies. The membrane was then incubated at 4 °C overnight with the primary antibody followed by HRP-labeled secondary antibody for 1 hour at room temperature. Informations for all used antibodies are listed in 2.1.6. Visualization was performed for strong signals with the Enhanced chemiluminescence (ECL) detection solution or for weak signals with the WesternBright™ Sirius™ Detection Kit (advansta, San José, USA) using the chemiluminescence detection system Evolution-Capt (Vilber Lourmat, Eberhardzell, Germany).

2.2.8.5 Nucleic acid extraction from panNET cell lines

Extraction of RNA from cultivated cell lines was performed using the RNeasy® Plus Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. To prevent the activity of ribonucleases, cells were scraped of the culture dish surface using 600 µl of a mix of RLTbuffer and β-mercaptoethanol (1:100, β-mercaptoethanol:RLTbuffer). In deviation of the manufacturer's protocol, all centrifugation steps were set to a minimum of 1 minute. Before elution of the RNA in 30 µl of water, the columns were centrifuged at 12,700 rpm for 5 minutes for further drying of the membrane. The isolated RNA was stored at -20 °C to -80 °C and for further investigation transcribed into cDNA (see 2.2.5.1 or 2.6.1).

2.2.8.6 Statistical analysis

Statistical analyses were achieved using Microsoft Excel (Microsoft Corporation, Redmond, WA, USA) and RStudio (Version 4.3.2). In total, three experiments were compared for each experimental set up and p-values ≤ 0.05 were considered significant with the following categories: * $p \leq 0.05$, ** $p \leq 0.01$, and *** $p \leq 0.001$. Visualization of data was carried out using Microsoft Excel and Inkscape (Version 1.3.2 Inkscape Project, 2020).

3. Results

3.1 The mTOR pathway is activated in a considerable number of panNET

Several studies have shown that the mTOR signaling pathway plays an important role in the pathogenesis of panNET (Chan & Kulke, 2014; Jiao et al., 2011). Particularly interesting in this context is the observation that between 33 to 52 % of panNET exhibit high mTOR pathway activity and that these cases are correlated with increased tumour cell progression and growth (Komori et al., 2014; Giuseppe Lamberti et al., 2018).

To identify tumours with activated mTOR signaling in the established cohort of 157 panNET cases, immunohistochemical staining was performed using a TMA. All selected patients were diagnosed with panNET between 1996 and 2019. They underwent at least one biopsy and the extracted tissue was archived in form of formalin-fixed paraffin-embedded tissue (FFPE) blocks. The cohort included 77 female patients (49 %) and 80 male (51 %) patients with an average age of 59 years

(age-span 18 to 88 years). The panNETs were classified using the TNM staging system (Klöppel et al., 2010), with 25 (16 %) of patients having stage I, 23 (15 %) stage II, 2 (1 %) stage III, and 19 (12 %) stage IV tumours. Staging could not be determined for 88 (56 %) patients due to data limitations. In addition to the staging, all tumours were classified according to the grading system of the WHO (Rindi et al., 2022), with 66 (42 %) being well-differentiated (G1), 60 (38 %) moderately differentiated (G2), and 14 (9 %) poorly differentiated (G3). Grading could not be determined for 17 (11 %) patients due to data limitations. The cohort included 34 functional tumours (22%), with 26 being insulinomas (16.6%), 5 being glucagonomas (3.2%), and 3 being gastrinomas (1.9%). A table of all clinic pathological features in the study population are listed in Table 4 (2.2.1).

As an indicator for the pathway activity, the phosphorylation status of the ribosomal protein S6 (pS6) was investigated (Figure 8). The protein has been described to be a good indicator of the mTOR pathway activity in studies on anal carcinomas and renal cell carcinomas (Knoll et al., 2016; Stelzer et al., 2010). The protein is mainly phosphorylated by different p70 and p90 ribosomal protein S6 kinases as well as the mTOR protein (Ruvinsky et al., 2005; Yi et al., 2021).

Figure 8: Immunohistochemical staining of panNETs using anti-pS6 antibody.

Representative immunohistochemical staining (brown) for the expression of pS6. Expression levels were quantified into four categories: No staining, low staining, medium staining and high staining based on the expertise of an experienced pathologist.

In this study, 22 % of the investigated panNETs showed alerted pS6 expression and therefore activation of mTOR signalling (Figure 9). That corresponds to 34 out of 157 cases, including 23 cases (15 %) with low mTOR pathway activity, 8 cases (5 %) with medium activity and 3 cases (2 %) with high mTOR activity (Figure 9).

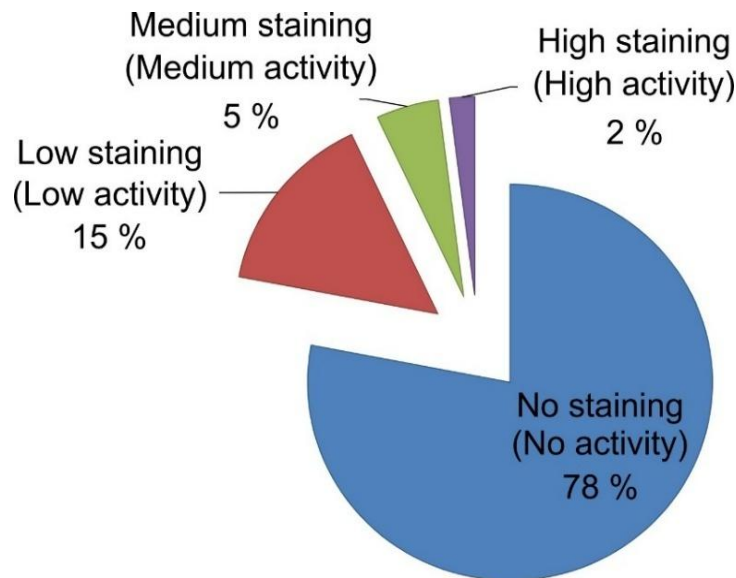

Figure 9: Activity of the mTOR signaling pathway in panNET.

The expression of pS6 was correlated to the mTOR signaling pathway activity in panNET. In total, 22 % of panNET had an activated mTOR signaling pathway. The activity was quantified into four categories: no activity, low activity, medium activity, high activity.

3.2 Molecular characterization of mitochondrial genomes in panNETs

Various somatic mutations of the mitochondrial DNA have been described in tumour entities (Schon et al., 2012; Stewart et al., 2015) and could be correlated with alerted mTOR pathway activity in different cancer cells as well as fibroblasts (Chung et al., 2021). Little is known about the occurrence of mtDNA mutations in panNET due to the low incidence of this entity. Therefore, one aim of the present work was to investigate mtDNA mutations in the established cohort using NGS-analysis and to study the impact of the mTOR pathway activity on these changes. Selected cases for this analysis included 21 mTOR-activated panNETs and 48 panNETs with no mTOR signaling (total 69 panNET). To distinguish inherited from somatic mtDNA mutations; tumour and normal tissue was sequenced and compared for each patient. The total of all cases examined and the corresponding somatic mutations of the mtDNA are listed in the supplementary Table S 1.

Figure 10: The mTOR signalling pathway activity has no impact on the detected mitochondrial mutations in panNET.

Somatic mutations within the mtDNA were detected using the QIAseq Targeted Panel DHS-105Z which covers the whole mitochondrial genome. In total, 69 panNETs were investigated, including 21 mTOR-activated panNET and 48 cases with no activation of the pathway. A) Heatmap of the identified mutations. All identified mitochondrial mutations were categorized in the following categories: Mutations of the ribosomal RNA (blue), missense-mutations (green), mutations within the non-coding region (red) and mutations of the tRNA (orange). B) Division of the investigated panNET according to the occurrence of the mutations of the mitochondrial genome and the activity of the mTOR signaling pathway.

28 out of 69 panNET (41 %) showed mutations within the mitochondrial genome (Figure 10). These cases included 12 (panNET with activated mTOR pathway signaling and 16 with no activation (Figure 10). Tumour-specific mutations were found in all regions of the mtDNA (non-coding region, genes coding for rRNAs, genes coding for tRNAs and genes coding for respiratory chain complexes) with the most frequent mutations occurring in genes for respiratory chain complexes (Figure 10). In summary, the spectrum of mutational variants varied widely among panNETs and was independent of the mTOR pathway activity.

3.3 Activated mTOR pathway leads to regulation of mitochondria related genes in panNET

One goal of this work was to investigate molecular alterations in panNET that are impacted by the activity of the mTOR signaling pathway. Therefore, RNA sequencing was performed on 69 panNETs. Selected cases for this analysis included 21 panNET with activated mTOR pathway and 48 panNET without mTOR activity.

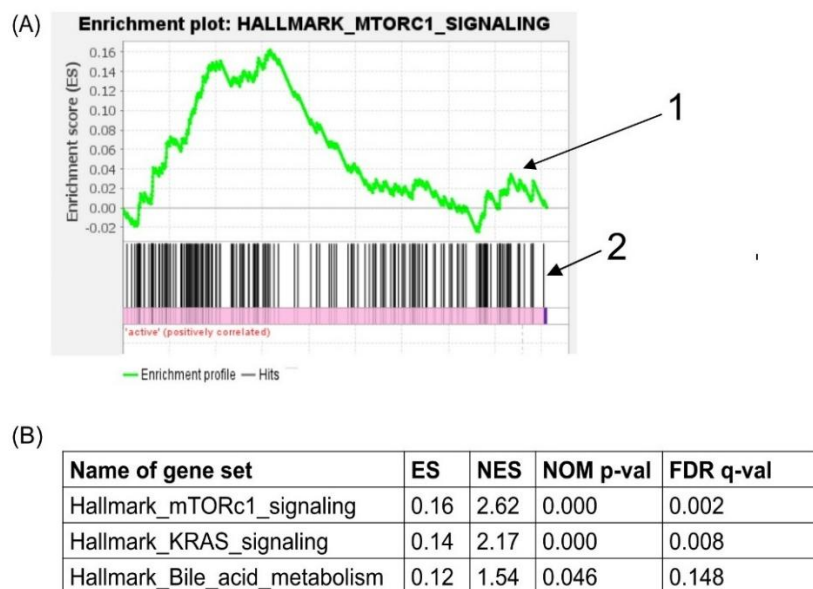

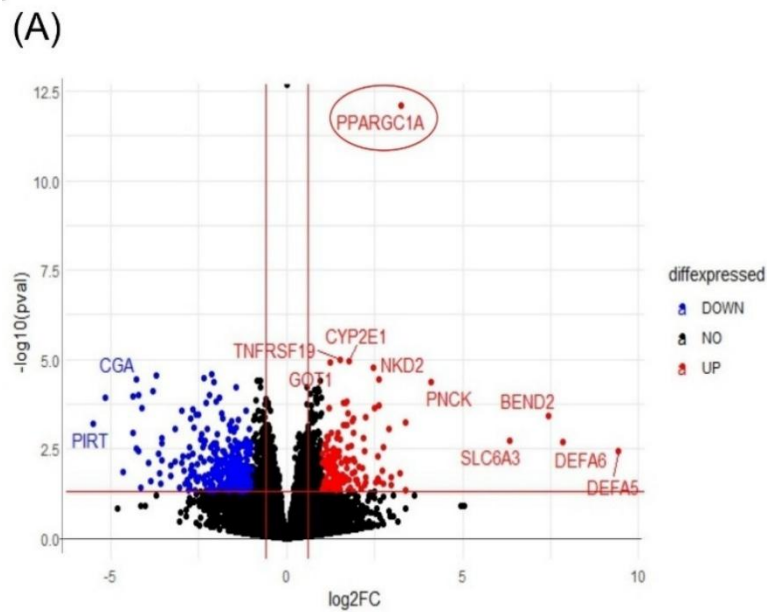

Figure 11: The mTOR activity impacts different pathways in panNET.

A) Enrichment plot of the mTORc1 gene set in panNET with high mTOR pathway activity. The green line (1) represents the running Enrichment score (ES) for the gene set as the analysis progresses through the ranked list. The black lines (2) highlight the positions of the gene set members within the ranked gene list. B) List of the top 3 gene sets enriched in panNET with high mTOR pathway activity. The ES reflects the degree to which a gene set is overrepresented at the top or bottom of a ranked list of genes. Normalized enrichment score (NES) represents enrichment score normalized across analyzed gene sets. Statistical significance is calculated by nominal p-value of the ES using an

empirical gene-set-based permutation test. A nominal p-value of 0.000 stands for an actual p-value of less than $1/\text{number-of-permutations}$ (in this work: $1/1000 = 0.001$). Gene sets from the MSigDB database were tested and gene sets with a false discovery rate (FDR) <0.25 and nominal p-value <0.01 were considered significantly enriched in a prior defined set of genes. All enriched gene sets are listed in the supplementary Table S2.

Gene Set Enrichment Analysis (GSEA) revealed 21 out of 50 hallmark gene sets that were impacted by the mTOR activity status in panNET (list of all enriched gene sets in supplementary Table S2). These 21 gene sets included 3 gene sets that were significantly enriched and 18 gene sets that were significantly decreased in panNET with activated mTOR pathway compared to panNET without activation (FDR < 0.25 ; nominal p-value < 0.05). As expected, the most significantly enriched hallmark pathway was the mTORc1 signaling pathway (FDR = 0.002; nominal p-value < 0.001 ; Figure 11). Differentially gene analysis was also performed comparing 21 panNET with activated mTOR pathway and 48 panNET without activation of mTOR. In total, 325 differentially expressed genes were identified comparing these two groups (padj < 0.05 ; list of all differentially expressed genes in the supplementary Table S 3). These differentially expressed genes included 46 significantly upregulated and 279 significantly downregulated genes in panNET with mTOR pathway activity compared to panNET without mTOR activity (padj < 0.05). The most significantly upregulated gene in panNET with mTOR pathway activity was the *PPARGC1A* gene that encodes for the PGC1 α protein (Wald test = 7.16; adjusted p-value < 0.001 ; Figure 12A, B). This protein is a transcriptional coactivator that plays a key role in the mitochondrial biogenesis through interaction with different transcription factors (Liang & Ward, 2006).

(B)

Gene	Protein	Wald test	adjusted p-val
PPARGC1A	PGC1 α	7.16	1.60E-08
LCN1	Lipocalin 1	4.94	2.60E-03
TNFRSF19	Tumor necrosis factor receptor superfamily, member 19	4.42	1.92E-02

Figure 12: Activated mTOR pathway results in increased expression of PGC1 α in panNETs.

A) Volcano plot of differentially expressed genes in panNET with activated mTOR pathway compared to panNET without activation of mTOR. Genes with a log2foldchange (log2FC) < -1 or > 1 and a pval < 0.05 were included in the plot. Genes that are down-regulated in panNET with mTOR pathway activity are shown in blue and genes that are upregulated in panNET with mTOR pathway activity are marked in red. B) List of the top 3 genes that are differentially regulated between panNET with activated mTOR pathway and panNET without activation. The genes were determined using the DESeq2 package. All genes with Benjamin Hochberg adjusted p-value (adjusted p-val) < 0.05 were included. The data are represented as Wald-statistic (Wald test). Genes with negative Wald-statistic values are down-regulated in panNET with mTOR pathway activity compared to panNET without activation and genes with positive values are upregulated. All differentially expressed genes are listed in the supplementary Table S 3.

In the second step of the differentially gene analysis, the panNET with mTOR pathway activity were further divided into two groups based on the grading of the cases. This resulted in 10 low grade panNET (G1) with mTOR pathway activity that were compared to 11 high grade panNET (G2 + G3) with mTOR pathway activity. In total, 131 differentially expressed genes were identified comparing these two groups,

including 111 upregulated and 20 downregulated genes in high grade panNET with mTOR activity ($p_{adj} < 0.05$; list of all differentially expressed genes in the supplementary Table S 4). The most significantly upregulated gene in high grade panNET (G2 + G3) compared to low grade panNET (G1) with mTOR pathway activity was the *HSPA9* gene that encodes for the protein mortalin (Wald test = 4.943; adjusted p-value < 0.001 ; Table 11). This protein is mainly localized to the mitochondria (around 70% of mortalin in the cell) and acts as a mitochondrial chaperon that impacts mitochondrial biogenesis, the formation of reactive oxygen species and glucose metabolism (Esfahanian et al., 2023).

Table 11: Activated mTOR pathway results in increased expression of mortalin in high-grade panNETs.

List of the top 3 genes that are differentially regulated between high grade (G2/G3) panNET with mTOR pathway activity and low grade (G1) panNET with mTOR pathway activity. The genes were determined using the DESeq2 package. All genes with Benjamin Hochberg adjusted p-value (adjusted p-val) < 0.05 were included. The data are represented as Wald-statistic (Wald test). Genes with negative Wald-statistic values are down-regulated in between high grade (G2/G3) panNET with mTOR pathway activity compared to low grade (G1) panNET with mTOR pathway activity and genes with positive values are upregulated. All differentially expressed genes are listed in the supplementary Table S 4.

Gene	Protein	Wald test	adjusted p-val
HSPA9	Mortalin	4.943	0.00019
ZNF702P	Putative zinc finger protein 702	4.903	0.00016
RNF187	Ring Finger Protein 187	4.829	0.00020

Using quantitative PCR it could be confirmed that the expression of *PPARGC1A* (PGC1 α) was 2 fold-changes higher in panNET with mTOR pathway activity (21 panNET) when compared to panNET without alerted mTOR activity (49 panNET; $p < 0,01$; Figure 13A). It could also be confirmed that the *HSPA9* (mortalin) expression was 1.3 fold-changes higher in high grade panNET (G2 + 3) with mTOR pathway activity (11 panNET) when compared to low grade panNET (G1) with mTOR pathway activity (10 panNET; $p < 0.05$; Figure 13B). These findings underline our results from the differentially gene analysis, identifying two mitochondria related genes as targets of mTOR in panNET.

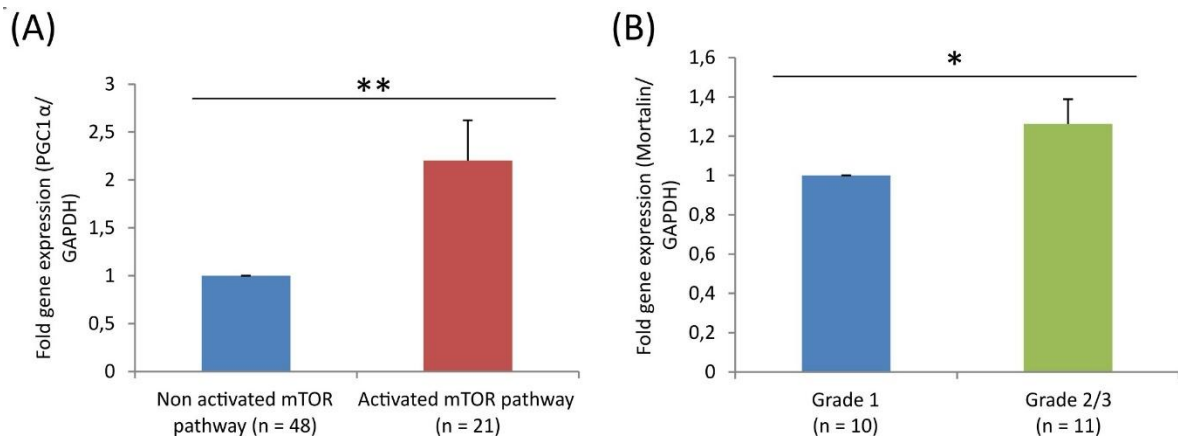

Figure 13: PGC1α and mortalin are targets of mTOR in panNET.

A) Gene expression of PGC1α was measured by qPCR analysis. The expression of the gene was compared between panNET without alerted mTOR pathway activity (non-activated mTOR) and panNET with mTOR pathway activity (activated mTOR). The control group was set to 1 for better representation. Values represent means ± SEM (**p≤0.01, ***p≤0.001; paired t-test (two-tailed)). B) Gene expression of *HSPA9* (mortalin) was measured by qPCR analysis. The expression of the gene was compared between low grade panNET with activated mTOR pathway (mTOR activated G1) and high grade panNET without activation of mTOR (mTOR activated G2/ 3). The control group was set to 1 for better representation. Values represent means ± SEM (**p≤0.01, ***p≤0.001; paired t-test (two-tailed)).

3.4 Regulation of the mTOR pathway activity leads to reduced *PPARGC1A* expression in BON1 cells

To further study the role of mTOR in gene expression of panNET, mTOR pathway activity was inhibited in the cell lines BON1 and QGP1 (Figure 14A - B) using everolimus and temsirolimus. These rapalogues mainly effect the activity of the mTORc1. Initially, the activity of the mTOR pathway was assessed by measuring pS6 expression through immunoblot analysis. Therefore, pS6 levels in BON1 and QGP1 cells were compared with those in two colorectal cancer cell lines (HCT116 and SW480), which are known to exhibit low mTOR pathway activity.

Figure 14: The mTOR pathway is activated in BON1 and QGP1 cell lines.

The activity of the mTOR signalling pathway was investigated using the cell lines BON1 (A) and QGP1 (B), which both originate from neuroendocrine tumours located in the pancreas. C) Representative western blot images for the expression of phosphorylated S6 (32 kDa). The expression of pS6 was correlated to the mTOR signaling pathway activity in panNET cell lines (BON1 and QGP1) and compared to the expression in colorectal cancer cell lines (HCT116 and SW480). The S6 protein (32 kDa) represents the unphosphorylated form of the protein. 30 µg protein was loaded per lane and actin (40 kDa) was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3.

As expected, elevated levels of pS6 were observed in both panNET cell lines (BON1 and QGP1) compared to the colorectal cancer cell lines (HCT116 and SW480), indicating the activation of mTOR signalling (Figure 14C). Western Blot analysis at 72 hours after the administration of either 1 µM everolimus or 1 µM temsirolimus revealed a reduction of the pS6 protein level by in BON1 60 to 70 % cells and by 50 % in QGP1 cells, indicating strong inhibition of mTOR signalling (Figure 15).

Figure 15: Inhibition of the mTOR signalling pathway in the panNET cell lines BON1 and QGP1.

A - B) Representative western blot images for the expression of phosphorylated S6 (32 kDa) in BON1 treated with the mTOR inhibitors Everolimus (1 μ M, 72 hours) or Temsirolimus (1 μ M, 7 hours). The S6 protein (32 kDa) represents the unphosphorylated form of the protein. 30 μ g protein was loaded per lane and actin (40 kDa) was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. C - D) Representative western blot images for the expression of phosphorylated S6 (32 kDa) in QGP1 treated with the mTOR inhibitors Everolimus (1 μ M, 72 hours) or Temsirolimus (1 μ M, 7 hours). The S6 protein (32 kDa) represents the unphosphorylated form of the protein. 30 μ g protein was loaded per lane and actin (40 kDa) was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. E) Quantification of the protein level of pS6 of the panNET cell lines BON1 and QGP1. Data are shown from three experiments and values represent means \pm SEM (* p \leq 0.05, ** p \leq 0.01; paired t-test (two-tailed)).

To dissect the molecular alterations induced by inhibition of the mTOR signalling pathway, RNA-sequencing was performed on BON1 and QGP1 cells treated with everolimus and temsirolimus. The wild type panNET cells and the panNET cells treated with DMSO served as a control.

In the first step, the general influence of mTOR inhibitors on the expression patterns of genes in panNET was investigated by generating a heatmap with hierarchical clustering for all samples (Figure 16A - B). The color coding of the heatmaps reflects the expression levels of each gene across the different samples, with yellow indicating higher expression and blue indicating lower expression (Figure 16A - B). The expression values were normalized and variance-stabilized to facilitate comparison between samples. Hierarchical clustering was indicated by a dendrogram at the top of each heatmap (Figure 16A - B). As expected, the clustering analysis distinguished the treatment groups (mTOR inhibitors) from the control groups (wild-type and DMSO-treated cells) in both panNET cell lines (BON1 and QGP1, Figure 16A – B). The group of panNET cells treated with everolimus formed a cluster alongside the temsirolimus- treated group, while the wild-type control group exhibited similarities with the DMSO-treated cells (Figure 16A - B). In addition to the heatmaps, a MA-plot was created by categorizing the samples into the two cluster groups: a control group (wild-type panNET cell line and panNET cells treated with DMSO) and an mTOR inhibitor group (panNET cells treated with everolimus or temsirolimus). The plot was used to provide an overview of the distribution of differential expressed genes between these cluster groups. Therefore, the log₂ fold change (M) of the differentially expressed genes was plotted against the mean of normalized counts (A, Figure 16C - D). Each point represents a single gene, and the color coding highlights genes with significant difference in expression between the control and mTOR inhibitor-treated groups in red ($p_{adj} \leq 0.05$, Figure 16C - D). Genes that did not exhibit significant changes are shown as grey points. The MA-plots revealed a clear distinction between the control and treatment groups. Taken together with the results from the heatmaps, this suggests a strong effect of the mTOR inhibitors on gene expression in panNET cell lines (Figure 16).

Figure 16: Inhibition of the mTOR pathway activity in panNET cell lines impacts the expression of various genes.

Differential expression analysis was performed using RNA sequencing in the panNET cell lines BON1 and QGP1. A - B) Heatmaps of gene expression data in BON1 (A) and QGP1 (B) cells with sample clustering. Rows represent genes, and columns represent samples. The colour intensity indicates the expression level of each gene in each sample. The value represents the normalized and variance-stabilized expression level of each gene, with darker colours (blue) indicating lower expression and brighter colours (yellow) indicating higher expression. A square root transformation was applied to the values to better highlight differences in lower and intermediate expression levels. The samples are hierarchically clustered based on their gene expression profiles, highlighting patterns of similarity across different experimental groups. Clusters of samples with similar expression profiles are grouped together, as indicated by the dendrogram. C – D) MA-plot of gene expression data in BON1 (C) and QGP1 (D) cells. The x-axis represents the mean of normalized counts, and the y-axis shows the log₂fold change between the control group (wild type panNET cells and cells treated with DMSO) and the group treated with the mTOR inhibitors everolimus and temsirolimus. Each point represents a gene, with red-highlighted points indicating genes with significant differential expression ($p_{adj} \leq 0.05$). A list of all differentially expressed genes is shown in the supplementary Table S 5 (BON1) and Table S 6 (QGP1).

Expression analysis of different genes was performed on the same groups as the MA-plot for both investigated panNET cell lines (BON1 and QGP1). Therefore, gene expression was compared between a control group (wild type panNET cells + DMSO) and a group treated with mTOR inhibitors (panNET cells treated with everolimus or temsirolimus). In general, differential gene analysis ($p_{adj} \leq 0.05$; differentially expressed genes are listed in supplementary Table S 5 and Table S 6) revealed 1897 regulated genes in BON1 cells and 1129 regulated genes in QGP1 cells treated with mTOR inhibitors. In the mTOR inhibitor group of the BON1 cell line, 923 genes were downregulated, and 974 genes were upregulated in comparison to the control group. In QGP1 cells treated with mTOR inhibitors, 609 genes were downregulated, and 520 genes were upregulated in comparison to the control group. A list of all differentially expressed genes is shown in the supplementary Table S 5 (BON1) and Table S 6 (QGP1). In accordance with the results of the differential gene analysis in NET tissue samples, the *PPARGC1A* gene was downregulated in the mTOR inhibitor group of the BON1 cell line compared to the control group (Wald test = -2.82; $p_{adj} < 0.001$). Using quantitative PCR it could be confirmed that the expression of *PPARGC1A* was 0.3 fold-changes lower in BON1 treated with mTOR inhibitors when compared to the control group (Figure 17A). Western Blot analysis at 72 hours after the administration of either 1 μ M everolimus or 1 μ M temsirolimus revealed a reduction of the PGC1 α protein level by 80 % in BON1 cells treated with mTOR inhibitors (Figure 17B - C). Contrary to the expectations, there were no evidence for an influence of the mTOR pathway activity on the *PPARGC1A* in QGP1 cells and mTOR activity had no impact on the expression of *HSPA9* ($p_{adj} > 0.05$).

Figure 17: Inhibition of the mTOR pathway activity results in decreased expression of PGC1 α in BON cells.

A) Gene expression of PGC1 α was measured by qPCR analysis. Cells were treated with 1 μ M everolimus or temsirolimus for 72 hours. The control group was set to 1 for better representation. Values represent means \pm SEM (** $p \leq 0.001$; paired t-test (two-tailed)). B) Representative western blot images for the expression of PGC1 α (130 kDa) in BON1 cells. Cells were treated with 1 μ M everolimus or temsirolimus for 72 hours. 30 μ g protein was loaded per lane and actin (40 kDa) was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. C) Representative western blot images for the expression of PGC1 α in BON1 cells. Cells were treated with 1 μ M everolimus or temsirolimus for 72 hours. 30 μ g protein was loaded per lane and actin was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. D) Quantification of the protein level of PGC1 α of the panNET cell line BON1. Data are shown from three experiments and values represent means \pm SEM (* $p \leq 0.05$; paired t-test (two-tailed)).

3.5 Reduced PGC1 α expression leads to reduced mTOR pathway activity in panNET cell lines

In the next step, both mTOR activated cell lines were treated with PGC1 α - and mortalin-specific siRNAs and the mRNA and protein levels of both targets were investigated by qPCR analysis and immunoblotting. As expected, all investigated cell lines (BON1, QGP1) treated with PGC1 α -specific siRNAs exhibited a reduction in *PGC1 α* mRNA by 50 – 80% ($p \leq 0.01$) in comparison to the control (Figure 18A). Moreover, the protein levels of PGC1 α were also reduced by 70 – 80% ($p \leq 0.05$) compared to the control (Figure 18C, E). Likewise, all investigated cell lines (BON1, QGP1) treated with mortalin-specific siRNAs exhibited a reduction in *HSPA9* mRNA by 50 – 60% ($p \leq 0.01$, Figure 18B) and reduced mortalin protein level by 50 – 60% ($p \leq 0.05$, Figure 18D, F). Interestingly, both siRNAs (mortalin, PGC1 α) appear to also influence the expression of the respective other protein. All investigated cell lines (BON1, QGP1) treated with PGC1 α -specific siRNAs also exhibited a reduction in *HSPA9* mRNA by 50 – 70% ($p \leq 0.05$, Figure 18A) and reduced mortalin protein level by 70 – 80% ($p \leq 0.05$, Figure 18C, E) in comparison to the control. Moreover, both panNET cell lines BON1 and QGP1 treated with mortalin-specific siRNAs showed reduced *PGC1 α* mRNA by 50 – 60% ($p \leq 0.05$, Figure 18B) and reduced PGC1 α protein level by 50 – 60% ($p \leq 0.05$, Figure 18D, E) in comparison to the control.

Figure 18: Reduced PGC1α expression leads to reduced mortalin expression in panNET cell lines and vice versa.

A – B) Quantification of the expression of PGC1α (A) and mortalin (B) in the panNET cell lines BON1 and QGP1. The expression of the genes was measured using qPCR analysis and normalized to the reference gene actin. Data were shown from three experiments and values represent means ± SEM

(*p≤0.05, **p≤0.01, ***p≤0.001; paired t-test (two-tailed)). C-D) Representative western blot images for the expression of PGC1α (130 kDa) (C) and mortalin (75 kDa) (D) of the panNET cell lines BON1 and QGP1. 30 µg protein was loaded per lane and actin was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. E-F) Quantification of the protein level of PGC1α (E) and mortalin (F) of the panNET cell lines BON1 and QGP1. Data are shown from three experiments and values represent means ± SEM (*p≤0.05, **p≤0.01, ***p≤0.001; paired t-test (two-tailed)).

As the main goal of this section of the work was to investigate the interaction between mTOR and the two mitochondria related proteins PGC1α and mortalin, it was investigated if these two proteins influence the expression of pS6 in the panNET cell lines BON1 and QGP1 by immunoblotting.

Figure 19: Reduced PGC1α expression impacts the mTOR pathway activity in panNET cell lines.

A-B) Representative western blot images for the expression of pS6 (32 kDa) in the panNET cell lines BON1 and QGP1. The S6 protein (32 kDa) represents the unphosphorylated form of the protein. 30 µg protein was loaded per lane and actin (40 kDa) was used as a loading control. All original, non-cleaved Western Blot images are shown in the supplementary Figure S 3. C) Quantification of the protein level of pS6 measured in the panNET cell lines BON1 and QGP1. Data are shown from three experiments and values represent means ± SEM (*p≤0.05, **p≤0.01, ***p≤0.001; paired t-test (two-tailed)).

The expression of pS6 and therefore the activity of mTOR was reduced by 50 – 60% ($p \leq 0.05$) in all investigated cell lines (BON1, QGP1) treated with PGC1 α -specific siRNAs in comparison to the control (Figure 19). In contrast, pS6 expression remained unaffected by mortalin-specific siRNA ($p > 0.05$, Figure 19). These findings suggest that, unlike mortalin, PGC1 α plays a regulatory role in mTOR signalling and should be further investigated as a potential functional modulator in pancreatic neuroendocrine tumour cells.

4. Discussion

4.1 Expression analysis of pS6 identifies 22 % of panNET with activated mTOR pathway

Pancreatic neuroendocrine tumours are a relatively rare malignancy, with their incidence increasing over the past decade from 0.42 per 100,000 people per year (2010-2011) to 1.39 per 100,000 people per year (2019-2020, Stensbøl et al., 2021). Due to the low incidence of this tumour type, treatment options are limited, and the therapy of patients remains challenging. The only known potential curative treatment is tumour surgery, which is mainly used for patients with primary, non-metastatic cases (Akirov et al., 2019; Ro et al., 2013; Storni et al., 2021). The success of this treatment depends on the localization, size, and metastatic state of the tumour. It is noteworthy, however, that surgery can also be performed for metastatic cancer, but in such cases, it serves as a palliative treatment aimed at disease control rather than a cure (PDQ Adult Treatment Editorial Board, 2024). In general, therapy of advanced panNETs mainly focuses on improvement of the patient's quality of life by controlling the disease. The two most common treatments in this context are chemotherapy and somatostatin analogues. Chemotherapy is used to prevent further tumour growth, while somatostatin analogues are administered to control symptoms (Megdanova-Chipeva et al., 2020; Ro et al., 2013). However, chemotherapy is associated with high toxicity, and while somatostatin analogues can effectively control symptoms, their antitumour activity is limited (Megdanova-Chipeva et al., 2020; Ro et al., 2013). Therefore, it is not surprising that the introduction of mTOR inhibitors as targeted therapy for panNETs, yield new opportunities for patients with advanced or metastatic tumours. These kind of inhibitors have mainly cytostatic effects, leading to

cell cycle arrest, reduced cell growth and cell proliferation in tumour cells (Exner et al., 2020). A study from Yao *et al.* showed that treatment with the first-generation inhibitor everolimus leads to longer progression-free survival in patients with advanced panNET (Yao et al., 2016). This study is one of the first long-term investigations showing that these inhibitors not only improve patients' quality of life and relieve symptoms but also have the potential to extend their lives by effectively slowing disease progression. Despite these promising findings, the treatment of patients with mTOR inhibitors remains challenging due to certain limitations. One of the major challenges is the lack of reliable biomarkers to guide mTOR-based therapy (Tian et al., 2019). In 2017, Yeung *et al.* highlighted the Kirsten Rat Sarcoma (KRAS) as a potential biomarker for the response of cancer cells to everolimus (Yeung et al., 2017). Their study found that KRAS mutations were associated with resistance to everolimus in 45 % of 20 advanced biliary tract cancer cell lines and this resistance was linked to the activation of the PI3K/AKT/mTOR signalling pathway (Yeung et al., 2017). However, there is still limited evidence and too few studies to consider KRas as a reliable biomarker for predicting resistance to mTOR inhibitors in clinical settings.

Another protein commonly used as an indirect marker for mTOR pathway activity in both research and clinical settings is the S6 protein. S6 is a component of the 40S small ribosomal subunit and acts as a RNA-binding protein in this context (Meyuhas, 2008; Yi et al., 2021). Among its various roles, S6 is involved in the translation of 5' oligopyrimidine tract mRNAs and the mTOR-mediated regulation of protein synthesis (Dufner & Thomas, 1999; Komori et al., 2014; Ruvinsky et al., 2005; Yi et al., 2021). S6 has been used for a long time as a marker of mTOR pathway activity in research studies involving anal carcinomas (Stelzer et al., 2010), prostate cancer cell lines (Mortensen et al., 2015), and bladder cancer (Svatek et al., 2019). Building on this, a recent genome-wide CRISPR/Cas9 screen identified interleukin enhancer binding factor 3 (ILF3) as an interaction partner of mTORC1 in the context of amino acid sensing, with mTORC1 activity being assessed by pS6 fluorescence (Yan et al., 2023). Moreover, a recent study on uterine leiomyosarcomas showed that aberrant PI3K/mTOR signaling plays a crucial role in immune evasion (Wispelaere et al., 2024), while another study on pediatric malformations of cortical development revealed that mutations in the mTOR pathway lead to dysregulation of different cellular functions (Bakouh et al., 2025), both using pS6 as an indicator of high mTOR

pathway activity. Additionally to the research studies, several clinical trials have utilized S6 as an indicator of mTOR pathway activity, including one of the first blinded studies on patients with sarcomas (Iwenofu et al., 2008), an early trial on glioblastoma (Cloughesy et al., 2008), and a more recent Phase II clinical trial on prostate cancer (George et al., 2020). While the sarcoma trial aimed to investigate S6 as a biomarker of mTOR activity, most clinical trials focus on exploring the potential benefits of first-generation mTOR inhibitors for patients, using S6 as a key biomarker. This makes S6 one of the most important proteins in this research area. However, it has not yet been demonstrated that pS6 serves as an indicator of mTOR activity in panNET. Our findings demonstrate a strong correlation between pS6 expression and mTOR pathway activation in panNET tissue, with 22% of cases showing elevated pS6 levels. These high pS6-expressing cases were further associated with an enrichment of genes related to the mTORC1 pathway during GSEA analysis. Additionally, pS6 expression was found to be upregulated in the panNET cell lines BON1 and QGP1 and treatment with rapalogues led to a 50-70 % decrease of these pS6 levels. Taken together, these findings suggest that pS6 could serve as a potential indicator of mTOR pathway activation in panNET, providing valuable insights for future therapeutic strategies targeting mTOR signaling in these tumors.

Interestingly, there has been recent discussion regarding the potential benefits of S6 kinase inhibitors in cancer patients, with some inhibitors being in preclinical or clinical trial stage (Artemenko et al., 2022). The first reported S6 inhibitor to reach Phase I trials was LY2584702, which has been tested as a monotherapy (Tolcher et al., 2014) or in combination with mTOR inhibitors (Hollebecque et al., 2014) in advanced solid tumours. Unfortunately, the inhibitor demonstrated limited efficacy and was discontinued due to unfavourable pharmacokinetics. However, it has paved the way for the development of other inhibitors, which have not reached clinical trial stages yet (Artemenko et al., 2022). A dual p70S6K/AKT inhibitor showed promising results in a Phase I trial for advanced breast cancer (Tsimberidou et al., 2021) and RNA-based therapies targeting S6, such as miRNA and lncRNA, are being explored (Ma et al., 2018). The present study could also pave the way for the development of more effective therapeutic strategies targeting the S6 pathway, potentially improving treatment outcomes for patients with mTOR pathway-driven cancers.

As we correlated the pS6 expression with the mTOR pathway activity in panNET, we

identified 22 % of tumours with activated mTOR pathway. Previous studies have reported mTOR activity in 33 to 52 % of panNET (Komori et al., 2014; G. Lamberti et al., 2017). The great variability between the percentages can be attributed to variations in study design, pre-existing conditions of patients, patient treatments, and consequently, the quality of the sample material used. While the present study focused solely on panNETs (both poorly and well-differentiated), Lamberti *et al.* exclusively examined tissue from patients with well-differentiated NETs originating from the pancreas and gastrointestinal tract (Giuseppe Lamberti et al., 2018). Furthermore, both Lamberti and Komori examined a smaller number of panNET cases compared to our cohort of 157 cases (Komori et al., 2014; G. Lamberti et al., 2017), which represents one of the largest cohorts studied to date.

4.2 The spectrum of mitochondrial mutations varied widely among panNET and was independent of mTOR signaling

The first somatic point mutations of the mtDNA were discovered by Polyak *et al.*, who analyzed the complete mitochondrial genome of ten colorectal cancer cell lines (Polyak et al., 1998). In the following years, numerous somatic mutations in the mitochondrial genome have been found, with the frequency of these somatic mtDNA mutations varying between different tumour entities (Schon et al., 2012; Stewart et al., 2015). A study of 31 tumour types showed that 59 % of cancer samples harbored at least one somatic mtDNA mutation (Ju et al., 2014), whereby another study on five different cancer types revealed that the frequencies of these deleterious tumour-specific somatic mutations ranged from 13% in glioblastomas to 63% in rectal adenocarcinomas (Larman et al., 2012). The mtDNA and mitochondria have also been shown to play an important role in neuroendocrine tumours. A study by Yang *et al.* investigated a cohort of neuroendocrine tumours and carcinomas and identified four molecular subtypes that differ in their genetic alterations, molecular landscape, and histo-pathological features (Yang et al., 2021). In particular, the Alpha cell-like subtype displayed significantly elevated mitochondrial parameters, including increased mitochondrial-protein content and higher expression of oxidative phosphorylation genes (Maluchenko et al., 2024; Yang et al., 2021). Despite these findings highlighting the importance of mitochondria in NETs, due to the low incidence and heterogeneity of panNET, little is known about the frequency of mtDNA mutations in this tumour type.

In the present study we found that 41 % of the investigated panNET harbour at least one somatic mutation of the mtDNA. The mutations were found in all regions of the mtDNA (non-coding region, genes coding for rRNAs, genes coding for tRNAs and genes coding for respiratory chain complexes) with the most frequent mutations occurring in genes for respiratory chain complexes. Interestingly, these mutations were independent of the mTOR pathway activity in panNET. A possible explanation could lie in the distinct mechanisms that regulate mitochondrial function and genomic stability. While the mTOR pathway plays a central role in regulating cell growth and survival, particularly through the control of autophagy and mitophagy (Bartolomé et al., 2017; Y. C. Kim & Guan, 2015; Qiao et al., 2022), the occurrence of mtDNA mutations depends on other, complex processes that go beyond the mTOR pathway. Although some mtDNA mutations are inherited across generations, a significant number develops over the course of a lifetime (Burr & Chinnery, 2024). In the case of cancer, it has been suggested that somatic mtDNA mutations are acquired during tumorigenesis, as they are absent in the adjacent non-cancerous tissue (Caldiran & Aydemir, 2024; Smith et al., 2022). Due to the lack of a protective histone structure and their proximity to the main site of ROS production in the cell, mtDNA mutations can arise from oxidative stress or damage induced by external agents (K. Chen et al., 2022; Roy et al., 2022; Shokolenko et al., 2009). Moreover, errors in mitochondrial DNA replication, disruptions in mitochondrial biogenesis as well as environmental factors can also cause mutations of the mtDNA (Craigén, 2012). All these processes can take place independently of the mTOR activity and therefore lead to the observed occurrence of mTOR-independent mtDNA mutations in panNET. Although it is still debated whether mtDNA mutations have tumor-promoting (Kim et al., 2016), tumor-suppressing (Iommarini et al., 2014), or neutral effects (Ju et al., 2014) on carcinogenesis, it is most often described that mtDNA mutations occur in cancer cells because they have special energy needs, due to their increased growth and proliferation rates (Hanahan, 2022). In many cases, these mutations lead to enhanced oxidative phosphorylation (OXPHOS), which boosts energy production and helps meet the increased demand (Hanahan, 2022). However, in the case of panNETs, a special scenario arises: A higher percentage of these tumours show increased mTOR pathway activity (Komori et al., 2014; G. Lamberti et al., 2017), which has been connected to high tumour growth and progression in different entities (Hua et al., 2019; Saxton & Sabatini, 2017). It is

possible that panNET cancer cells are not only relying on mitochondrial changes and OXPHOS to meet their elevated energy needs, but are also utilizing mTOR-mediated mechanisms, such as the activation of metabolic pathways for energy production. This could explain why no direct correlation between mTOR activity and mtDNA mutations was observed in our study. The panNETs seem to be using alternative mechanisms for energy supply, allowing mtDNA mutations to occur independently of mTOR pathway activation.

Another possible explanation for the lack of association between mTOR and mtDNA mutations could be that the treatment of patients may have influenced the results. Studies have shown that mTOR inhibition can reduce mtDNA mutations. For example, a study by Chung *et al.* demonstrated that one of the most common disease associated mtDNA mutations, the m.3243 A>G mutation, leads to upregulation of the PI3K-AKT-mTORC1 axis and that inhibition of the mTOR signalling pathway results in reduced mtDNA mutant load in tissue and cell culture experiments (Chung et al., 2021). Similarly, Dai *et al.* showed that rapamycin reduced the G11778A mutation associated with Leber's hereditary optic neuropathy in cybrid cells (Ying Dai et al., 2014). However, since our study lacked sufficient data on whether patients were treated with mTOR inhibitors, it is challenging to determine whether such treatments may have influenced the correlation between mTOR and mtDNA mutations in our cohort.

4.3 Identification of PGC1 α as a target of mTOR in panNET with activated mTOR pathway signalling

The next step was to dissect the molecular alterations that were induced by activation of the mTOR signaling pathway in panNET. It is known that mTOR impacts a variety of mRNAs related to nucleus encoded mitochondrial proteins, including mRNAs encoding for components of the oxidative phosphorylation and proteins that are involved in the transcription and translation of the mtDNA (Larsson et al., 2012). For instance, mTORc1 has been shown to regulate the transcription of mitochondrial mRNAs by inhibiting the 4E-binding proteins (4E-BPs) (Morita et al., 2013). This early discovery revealed that mTORC1 affects the expression of mitochondrial ribosomal proteins, components of complexes I and V of the oxidative phosphorylation pathway, as well as the transcription factor TFAM (Morita et al., 2013). More recent studies also underline the role of mTORC1 in regulating

mitochondrial translation. For example, investigations in primary human trophoblast cells demonstrate that inhibition of the mTOR pathway affects the expression of various proteins related to mitochondria and oxidative phosphorylation (OXPHOS) (Rosario et al., 2019; Rosario et al., 2020). Although there has been no direct connection between mTORC2 and the transcription of mitochondrial mRNAs, there is some evidence suggesting that this complex might also influence this process. For instance, mTORC2 has been shown to interact with key molecules such as AKT and Connexin 43, which play significant roles in cellular metabolism or act as structural proteins (Bantug et al., 2018; S. Wang et al., 2022). These interactions have been shown to impact the regulation of mitochondrial gene expression, contributing to mitochondrial integrity and the maintenance of energy homeostasis (Bantug et al., 2018; S. Wang et al., 2022).

One interesting protein family that has been described to connect mTOR and mitochondria in NET before, is the PGC1 family, with PGC1 α being the most well-known representative. PGC1 α is a 91 kDa protein that is encoded by the *PPARGC1A* gene which consist of 13 exons and is locates on chromosome 4p15.2 (Liang & Ward, 2006). The protein is located in the nucleus and mainly expressed in tissue with high energy demand as it is involved in metabolic key processes, like mitochondrial biogenesis, glucose metabolism and adaptive thermogenesis (Liang & Ward, 2006). PGC1 α interacts with at least 20 different nuclear factors and alternative splicing leads to several tissue-specific isoforms of PGC1 α , whereby all these isoforms act as transcriptional coactivators (Liang & Ward, 2006; Martínez-Redondo et al., 2015; Mastropasqua et al., 2018; Villena, 2015). In general, members of the PGC1 family are connected to different disease besides cancer, including neurodegenerative diseases, metabolic disorders or cardiovascular diseases (Qian et al., 2024). Interestingly, a study postulates that a considerable number of patients with small cell neuroendocrine tumours exhibit high expression of PGC1 α (Varuzhanyan et al., 2024). Varuzhanyan *et al.* showed that high expression of PGC1 α leads to enhanced OXPHOS and that PGC1 α influences both the progression and subtype determination of small cell neuroendocrine tumours (Varuzhanyan et al., 2024). In the present study, we were able to identify PGC1 α as a partner of the mTOR signaling pathway in panNET. The *PPARGC1A* was the most significantly upregulated gene in panNET tissue samples with activated mTOR

pathway and inhibition of mTOR led to reduced PGC1 α expression in the panNET cell line BON1. Interestingly, we couldn't find any changes in the expression of the protein after inhibition of mTOR in the panNET cell line QGP1. Studies performing comprehensive characterizations of both cell lines revealed significant similarities between them, with one notable difference found in the RAS-pathway between BON1 and QGP1 (Luley et al., 2020; Vandamme et al., 2015). This pathway is a crucial cellular pathway involved in regulating cell growth, cell survival and cell differentiation (Bahar et al., 2023). It is activated by different RAS proteins, which are expressed in various tissues, vary in the frequency of mutations in certain cancers, and have different relevance in specific diseases (Bahar et al., 2023). All RAS proteins act as molecular switches that activate various downstream kinases, such as RAF, MEK, and ERK, that control gene expression and cell functions (Bahar et al., 2023). In the present study, BON1 cells harbor a NRAS mutation, while QGP1 cells carry a KRAS mutation (Vandamme et al., 2015). Mutations in RAS genes are known to drive aberrant activation of downstream signaling cascades, including the PI3K/AKT/mTOR and MAPK/ERK pathways (Prior et al., 2012). These signaling networks can cross-regulate one another and impact the cellular response to mTOR inhibition. In BON1 cells, the NRAS mutation may lead to a more direct and robust activation of the mTOR pathway, making the cells more responsive to mTOR inhibition. Consequently, inhibition of mTOR could more effectively reduce PGC1 α expression in these cells. On the other hand, the KRAS mutation in QGP1 cells could activate different compensatory pathways, such as the PI3K/AKT or MEK/ERK axes, which might override or diminish the effect of mTOR inhibition on PGC1 α expression. These alternative pathways could maintain cellular homeostasis and prevent a significant decrease in PGC1 α levels despite mTOR pathway inhibition. Interestingly, we observed that mTOR inhibition by rapalogues was more effective in BON1 cells at the protein level, with a 60–70% reduction in pS6 expression, compared to a 50% reduction in QGP1 cells. This suggests that KRAS mutations in QGP1 cells might contribute to partial resistance to mTOR inhibition. This hypothesis is further supported by findings from Yeung *et al.* (2017), who demonstrated that KRAS mutations were associated with resistance to everolimus in 45% of 20 advanced biliary tract cancer cell lines (Yeung et al., 2017). In the present study, not only did mTOR seem to influence PGC1 α , but PGC1 α also

appeared to have an impact on mTOR signaling. We showed that PGC1 α was highly expressed in mTOR-activated panNETs, and that reduction of PGC1 α by siRNA led to a 50-60 % reduction in pS6 expression in panNET cell lines. Therefore, PGC1 α appears to be more than just a downstream target of mTOR; the reciprocal interaction between these two pathways points to a more dynamic relationship. Previous studies have also described this mTOR-PGC1 α axis in various cancer types and biological processes. For example, in lung epithelial cells, the mTOR/PGC1 α / β axis was found to be upregulated in senescent cells (Summer et al., 2019), suggesting that this pathway may contribute to cellular aging and senescence. Summer *et al.* proposed that targeting this axis could be beneficial for patients, though preclinical studies have produced mixed results (Houssaini et al., 2018; Summer et al., 2019). Moreover, recent studies of Infectious spleen and kidney necrosis virus and miscarriages have highlighted the involvement of the mTOR-PGC1 α axis in regulating cellular metabolism and stress responses (X. Fu et al., 2022; Zhu et al., 2024). In ISKNV-infected cells, mTOR activation promotes the PGC-1 α /SIRT3 pathway, influencing viral replication (X. Fu et al., 2022). Similarly, in miscarriage tissue, the mTOR/PGC1 α axis is implicated in mitochondrial dysfunction and cell apoptosis, leading to pregnancy loss (Zhu et al., 2024). In addition, the mTOR/PGC1 α axis is involved in key metabolic processes such as cellular reprogramming and gluconeogenesis. For instance, studies have shown that suppression of mTORc1 and PGC1 α is crucial for mitochondrial remodeling during somatic cell reprogramming (L. Wang et al., 2020). Additionally, mTORc1 plays a critical role in regulating hepatic gluconeogenesis through PGC1 α (G. Wang et al., 2022), highlighting the importance of this pathway in energy metabolism and metabolic diseases. Taken together, these studies underscore that the mTOR-PGC1 α axis plays a critical role in various pathophysiological conditions, presenting a potential therapeutic target across multiple diseases.

4.4 Identification of mortalin as a target of mTOR in high grade panNET with activated mTOR pathway

To not only dissect molecular alterations that were induced by activation of the mTOR signaling pathway in panNET but to also investigate them in the context of clinic pathological features, high grade (G2/G3) panNET tissue samples with mTOR pathway activity were compared against low grade (G1) panNET tissue samples with

mTOR pathway activity. We identified the *HSPA9* gene as the most upregulated gene in high grade (G2/G3) panNET tissue samples with mTOR pathway activity. In general, *HSPA9* encodes the protein mortalin, which is a member of the HSP70 subfamily. This family is a group of molecular chaperones that are involved in protein folding, regulation of apoptosis and cell survival (Bhattacharya et al., 2020; Esfahanian et al., 2023; Radons, 2016). Although the majority of HSP70 family members share similar structural characteristics, mutations in their coding regions determine their organelle specificity (McCallister et al., 2015). Mortalin contains a mitochondrial-targeting signal peptide at the N terminus, which makes it not surprising that 70 % of the protein is located in the mitochondria (Dahlseid et al., 1994; Esfahanian et al., 2023). In general, mortalin plays a crucial role in mitochondrial processes through the folding and stabilization of nuclear-encoded mitochondrial proteins and has an impact on different cancer related processes (Esfahanian et al., 2023). For instance, mortalin can bind with p53, a tumour suppressor that is frequently mutated in different cancer types, thereby promoting tumour growth and formation (Sabapathy & Lane, 2019). The binding of mortalin to p53 prevents the tumour suppressor from being transported to the nucleus, impairing its tumour-suppressive functions (Elwakeel, 2022; Gestl & Anne Böttger, 2012). This is in accordance with the observation, that mortalin is upregulated in different tumour types, like breast cancer (R. Zhang et al., 2021), gastric cancer (Yi Dai et al., 2021) or colorectal cancer (Javid et al., 2022), diminishing the overall survival of patients (Esfahanian et al., 2023; Yoon et al., 2022). Moreover, in medullary thyroid carcinoma (a neuroendocrine tumour) reduction of mortalin leads to cell death and decreased proliferation in cell culture experiments (D. Starenki et al., 2015). In line with our findings that mortalin is primarily upregulated in high-grade panNETs with mTOR pathway activity, it has been shown that the upregulation of this protein affects not only patient survival but also tumorigenesis and tumour progression to a more aggressive phenotype (Kaushal et al., 2024).

In contrast to mortalin in cancer, little is known about the relationship between mTOR and the protein so far. A study revealed that loss of mortalin function induces mitochondrial stress and apoptosis in different human cell lines (Burbulla et al., 2014). Burbulla *et al.* postulate that this effect can be rescued by the PTEN-induced kinase 1 (PINK1) in cells with a functional autophagic machinery (Burbulla et al., 2014). Interestingly, this protective effect of PINK1 has been observed in cells

treated with the mTOR inhibitor rapamycin (Sarkar & Rubinsztein, 2008), a compound that inhibits mTORC1 and induces autophagy, suggesting that mTOR may influence the autophagic response to mortalin loss. Taken together, our results highlight that mortalin is not only a critical player in mitochondrial function but also a key regulator within the mTOR signaling pathway in high-grade panNETs, suggesting that targeting mortalin or its interactions with mTOR could offer promising therapeutic strategies for these aggressive tumors.

It is noteworthy that PGC1 α , which we show to be generally upregulated in panNET with high mTOR pathway activity, has been reported to correlate with mortalin in some studies. For example, a study by Starenki *et al.* investigated the effect of the mortalin inhibitor MKT-077 on medullary thyroid carcinoma (MTC), a type of neuroendocrine tumour (Dmytro Starenki & Park, 2015). The study found that, in some MTC cells, inhibition of mortalin led to a decrease in the expression of PGC1 α , along with other markers of mitochondrial integrity (Dmytro Starenki & Park, 2015). Additionally, another study by Cai *et al.* showed that a decrease in PGC1 α in neuroblastoma cells resulted in a reduction of mortalin expression (Cai *et al.*, 2020). Taken together, these studies suggest a complex relationship between PGC1 α and mortalin, where changes in one may influence the expression of the other, highlighting their potential interconnected roles in mitochondrial integrity and neuroendocrine tumour biology.

Based on the observation that Mortalin, unlike PGC1 α , does not influence pS6 expression in cell culture experiments, it is possible that Mortalin could be a downstream target of mTOR. Additionally, in the tumour microenvironment, factors such as hypoxia or nutrient deprivation could impact mTOR activity and, consequently, the regulation of mortalin in ways that differ from standard cell culture conditions. These stress factors could lead to a differentiated regulation, affecting the direct relationship between mortalin and pS6 observed in specific experiments.

5. Conclusion and future directions

The mTOR signalling pathway plays an important role in targeted drug therapy for panNET, and there has been ongoing discussion about the potential benefits of combination therapy with mTOR inhibitors and drugs targeting mitochondrial pathways. However, investigating this question has proven challenging due to the rarity of panNET, which results in a limited number of available research samples. As

a consequence, our understanding of the impact of mTOR activity on the molecular characteristics of this cancer remains insufficient. In the present study, we established one of the largest cohorts to date, consisting of 157 cases. Despite the challenges in finding reliable biomarkers for mTOR treatment, we identified that 22% of panNET cases with activated mTOR pathway. Additionally, our study demonstrates that pS6 serves as a reliable biomarker for mTOR pathway activity in this tumour entity. Although we did not find any correlation between mTOR signalling activity and somatic mutations in the mtDNA, we successfully identified several mitochondria-related targets of mTOR in panNET. Notably, the most significantly upregulated gene in panNET with mTOR pathway activity was *PPARGC1A*, which encodes PGC1 α . This protein is described as the master regulator of mitochondrial biogenesis and has been investigated in some NET before but never in combination with the mTOR pathway activity. Interestingly, cell culture experiments showed that PGC1 α also influences the mTOR pathway activity of panNET. Given the possibility that PGC1 α may not only be regulated by mTOR but also influence mTOR pathway activity in panNET, future studies should focus on the molecular mechanisms underlying this interaction. Investigating whether PGC1 α acts as a downstream target of mTOR or if its role in the mTOR-PGC1 α axis involves a reciprocal feedback loop will be crucial in understanding the broader implications for targeted therapies. Additionally, exploring the impact of mTOR-PGC1 α interaction on mitochondrial function and panNET progression could provide new insights into potential therapeutic strategies, especially in combination therapies targeting both mTOR and mitochondrial pathways. In addition, mortalin could be identified as a target of mTOR in high-grade mTOR activated panNET in this study. Mortalin is also a mitochondria-related protein that has been associated with aggressive characteristics in other tumour entities. In contrast to PGC1 α , mortalin did not affect the mTOR pathway activity in panNET cell lines, indicating that it could be a downstream target of mTOR.

Overall, this study not only highlights key molecular targets involved in mTOR pathway activity but also opens the door to future research on the complex interplay between mTOR signalling and mitochondrial functions in panNET. Investigating this axis in greater detail may provide valuable insights for the development of more effective, targeted therapeutic strategies for this rare and challenging cancer.

Advanced fields Show

Figure S 2: System settings for GSEA.

The analysis was performed using the GSEA software provided by Broad Institutes.

Figure S 3: Original, non-cleaved Western Blot images.

The red boxes indicate the regions of the original blots used for the main figures. A) The image shows the original Western Blot for the detection of pS6 in the main figure 15A. Due to secondary antibodies

from different host species, pS6 (rabbit) and S6 (mouse) could be detected on the same membrane without any signal interferences. Due to secondary antibodies from different host species and different molecular weights, pS6 (rabbit, 35 kDa) and Actin (mouse, 40 kDa) could be detected on the same membrane without any signal interferences. B) The image shows the original Western Blot for the detection of pS6 in the main figure 15B. The sample 1 was excluded from the main figure. C) The image shows the original Western Blot for the detection of S6 in the main figure 15C. The sample 1 was excluded from the main figure. D) The image shows the original Western Blot for the detection of pS6 in the main figure 15D. E) The image shows the original Western Blot for the detection of S6 in the main figure 15E. F) The image shows the original Western Blot for the detection of PGC1 α in the main figure 17B. The sample 1 was excluded from the main figure. For a better understanding, the Western Blot image has been mirrored in the main figure. G) The image shows the original Western Blot for the detection of PGC1 α (BON1 cell line) in the main figure 17C. The samples 1 - 3 were excluded from the main figure. The shown blot is the same blot as in F, but other samples of the blot are focused. H) The image shows the original Western Blot for the detection of PGC1 α (QGP1 cell line) in the main figure 17C. The samples 1 and 2 were excluded from the main figure. For a better understanding, the Western Blot image has been mirrored in the main figure. I) The image shows the original Western Blot for the detection of Mortalin (BON1 cell line) in the main figure 17D. The samples 1 - 4 were excluded from the main figure. For a better understanding, the Western Blot image has been mirrored in the main figure. J) The image shows the original Western Blot for the detection of Mortalin (QGP1 cell line) in the main figure 17D. The samples 1 - 3 were excluded from the main figure. For a better understanding, the Western Blot image has been mirrored in the main figure. K) The image shows the original Western Blot for the detection of pS6 in the main figure 19A. Due to secondary antibodies from different host species, pS6 (rabbit) and S6 (mouse) could be detected on the same membrane without any signal interferences. Due to secondary antibodies from different host species and different molecular weights, pS6 (rabbit, 35 kDa) and Actin (mouse, 40 kDa) could be detected on the same membrane without any signal interferences. L) The image shows the original Western Blot for the detection of pS6 in the main figure 19B. Due to secondary antibodies from different host species, pS6 (rabbit) and S6 (mouse) could be detected on the same membrane without any signal interferences. Due to secondary antibodies from different host species and different molecular weights, pS6 (rabbit, 35 kDa) and Actin (mouse, 40 kDa) could be detected on the same membrane without any signal interferences.

Table S 1: List of all mtDNA mutations detected in the panNET collective.

All cases with activated mTOR pathway are marked in grey.

Table S 2: Gene sets enriched in panNET with high mTOR pathway activity.

Enrichment score (ES) reflects the degree to which a gene set is overrepresented at the top or bottom of a ranked list of genes. Normalized enrichment score (NES) represents enrichment score normalized across analyzed gene sets. Statistical significance is calculated by nominal p-value of the ES using an empirical phenotype-based permutation test. Gene sets from the MSigDB database were tested and gene sets with a false discovery rate (FDR) <0.25 and nominal p-value <0.01 were considered significantly enriched in a prior defined set of genes. A nominal p-value of 0.000 stands for an actual p-value of less than 1/number-of-permutations (in this work: 1/1000 = 0.001).

Name of gene set	ES	NES	NOM p-val	FDR q-val

Table S 3: List of genes that are differentially regulated between panNET with high mTOR pathway activity and panNET without activation.

The genes were determined using the DESeq2 package. All genes with Benjamin Hochberg adjusted p-value (padj) < 0.05 were included. The data are represented as Wald-statistic (stat). Genes with negative Wald-statistic values are down-regulated in panNET with high mTOR pathway activity compared to panNET without activation and genes with positive values are upregulated.

$$\text{Wald - statistic} = \frac{\log_2\text{FoldChange}}{\text{standard error of } \log_2\text{FoldChange}}$$

Table S 5: List of genes that are differentially regulated between BON1 cells treated with the mTOR inhibitors everolimus and temsirolimus and the control.

For simplified evaluation, the control group included wild-type BON1 cells and BON1 treated with DMSO, while the inhibitor group included BON1 cells that were treated with 1 μ M everolimus and temsirolimus for 72 hours. The genes were determined using the DESeq2 package. All genes with Benjamin Hochberg adjusted p-value (padj) < 0.05 were included. The data are represented as Wald-statistic (stat). Genes with negative Wald-statistic values are down-regulated in BON1 cells treated with mTOR inhibitors compared to the control group.

$$\text{Wald – statistic} = \frac{\log_2\text{FoldChange}}{\text{standard error of } \log_2\text{FoldChange}}$$

Table S 6: List of genes that are differentially regulated between QGP1 cells treated with the mTOR inhibitors everolimus and temsirolimus and the control.

For simplified evaluation, the control group included wild-type QGP1 cells and QGP1 treated with DMSO, while the inhibitor group included QGP1 cells that were treated with 1 μ M everolimus and temsirolimus for 72 hours. The genes were determined using the DESeq2 package. All genes with Benjamin Hochberg adjusted p-value (padj) < 0.05 were included. The data are represented as Wald-statistic (stat). Genes with negative Wald-statistic values are down-regulated in QGP1 cells treated with mTOR inhibitors compared to the control group.

$$\text{Wald - statistic} = \frac{\log_2\text{FoldChange}}{\text{standard error of } \log_2\text{FoldChange}}$$

Acknowledgment

I would like to take this opportunity to thank all those who supported me in the preparation of this dissertation:

- Professor Dr. Wilfried Roth for the opportunity to carry out my dissertation at the Institute of Pathology and for his support during this project.
- Dr. Nils Hartmann for the interesting choice of topic, as well as for the support in planning, conducting, and analyzing my work.
- Dr. Katrin Tagscherer for allowing me to carry out the cell culture experiments of my dissertation in her research group and for her support in planning and conducting the study.
- Professor Dr. Hans Zischler for taking on the secondary review.

I would also like to thank all the members of the Hartmann and Tagscherer research groups for their helpfulness and friendliness.

Special thanks to Doris Dreis, who helped me with all tissue-related experiments with great patience and advice, Dr. Michael Kloth and Nadine Dexheimer, who helped me with the RNA-sequencing experiments and analysis, Dr. Daniel-Christoph Wagner, who helped me with analysis of the TMA, Celine Müller, for providing her code for the analysis of the RNA sequencing and Jutta Richter, who helped me with cell culture experiments.

My thanks also go to the Biobank of the University Medical Center in Mainz for performing the TMA and to the Wilhelm Sander Foundation for funding this work.

Lastly, my thanks go to my family and friends, who supported and motivated me during this time.

Lebenslauf

Persönliche Angaben

Jessika Buchwaldt

Geburtsdatum: 18.07.1995

Akademischer Werdegang

Oktober.2020 – 2025:

Doktoratsstudium an der Johannes Gutenberg-Universität Mainz, Fachbereich Biologie am Institut für Pathologie

April.2018 – Juli.2020:

Master of Science in Biologie an der Johannes Gutenberg-Universität Mainz, Fachbereich Biologie am Institut für Pathologie

Oktober.2014 – August.2018:

Bachelor of Science in Biologie an der Johannes Gutenberg-Universität Mainz, Fachbereich Biologie am Institut für Pathobiochemie

Berufserfahrung

Oktober.2020 – Dezember.2025:

Wissenschaftliche Mitarbeiterin am Institut für Pathologie, Universitätsmedizin der Johannes Gutenberg-Universität Mainz

Juni.2018 – Januar.2019:

Wissenschaftliche Mitarbeiterin am Institut für Pathobiochemie, Universitätsmedizin der Johannes Gutenberg-Universität Mainz

Curriculum Vitae

Personal Information

Jessika Buchwaldt

Date of Birth: July 18, 1995

Academic Background

October 2020 – 2025:

Doctoral studies in Biology at the Institute of Pathology, Johannes Gutenberg University Mainz

April 2018 – July 2020:

Master of Science in Biology at the Institute of Pathology, Johannes Gutenberg University Mainz

October 2014 – August 2018:

Bachelor of Science in Biology at the Institute of Pathobiochemistry, Johannes Gutenberg University Mainz

Professional Experience

October 2020 – December 2025:

Research Associate at the Institute of Pathology, University Medical Center of the Johannes Gutenberg University Mainz

June 2018 – January 2019:

Research Associate at the Institute of Pathobiochemistry, University Medical Center of the Johannes Gutenberg University Mainz

Eidesstattliche Erklärung

Hiermit versichere ich, dass ich diese Dissertation selbstständig verfasst und keine anderen als die angegebenen Quellen und Hilfsmittel benutzt habe. Außerdem versichere ich, dass diese Arbeit weder in der jetzigen noch in einer abgewandelten Form bei einem anderen Prüfungsausschuss vorgelegt wurde.

Mainz, den _____
